

## Probabilistic Artificial Intelligence

### Active Learning

Here we are interested in choosing the next input point  $\mathbf{x}$  that some expert should label  $y$ . **Goal:** we want to choose the observations that provides us with the biggest gain of information/reduction in uncertainty.

### Markov Decision Processes

Machine Learning Appendix

Model Assessment and Selection

**Definition 3.1 Statistical Inference:** Is the process of deducing properties of an underlying probability distribution by mere analysis of data.

**Definition 3.2 Model Selection:**  
Is the process of selecting a model  $f$  from a given or chosen class of models  $\mathcal{F}$

**Definition 3.3 Hyperparameter Tuning:** Is the process of choosing the hyperparameters  $\theta$  of a given model  $f \in \mathcal{F}$

**Definition 3.4 Model Assessment/Evaluation:** Is the process of evaluating the performance of a model.

**Definition 3.5 Overfitting:**  
Describes the result of training/fitting a model  $f$  to closely to the training data  $\mathcal{Z}^{\text{train}}$ .  
That is, we are producing overly complicated model by fitting the model to the noise of the training set.  
**Consequences:** the model will generalize poorly as the test set  $\mathcal{Z}^{\text{test}}$  will not have not the same noise  
 $\Rightarrow$  big test error.

**Definition 3.6 Training Set  $\mathcal{Z}^{\text{train}}$ :** Is the part of the data that is used in order to train the model i.e. part of data which is used in order to update the weight according to the loss.

**Definition 3.7 Validation Set  $\mathcal{Z}^{\text{val}}$ :** Is the part of the data that is used in order to evaluate different hyperparamters.

**Definition 3.8 Test Set  $\mathcal{Z}^{\text{test}}$ :** Is part of the data that is used in order to test the performance of our model.

Move next section to statistical perspective section or merge it somehow

1.1. Core Problem of Statistical Inference

We assume that our data is generated by some probability distribution:

$$(\boldsymbol{x}_1, y_1), \dots, (\boldsymbol{x}_n, y_n) \stackrel{\text{i.i.d.}}{\sim} f$$

and we want to calculate the expectation of some statistic e.g. the expected loss:

$$\mathcal{R}(f) = \int \int_{\mathcal{X} \times \mathcal{Y}} f(\boldsymbol{x}, y) l(y, f(\boldsymbol{x})) \, \mathrm{d}y \, \mathrm{d}\boldsymbol{x}$$

**Problem:** we do not know  $f(\boldsymbol{x}, y) \Rightarrow$  can only estimate the **empirical risk** of this statistic:

$$\hat{\mathcal{R}}(f) := \frac{1}{n} \sum_{i=1}^n l(y_i, f(\boldsymbol{x}_i))$$

Questions

- ① How far is the true risk  $\mathcal{R}(f)$  from the empirical risk  $\hat{\mathcal{R}}(f)$ , for a given  $f$
- ② Given a chosen hypothesis class  $\mathcal{F}$ . How far is the minimizer of the true cost way from the minimizer of the empirical cost

$$f^*(\boldsymbol{x}) \in \arg \min_{f \in \mathcal{F}} \mathcal{R}(f) \quad \text{vs.} \quad \hat{f}(\boldsymbol{x}) \in \arg \min_{f \in \mathcal{F}} \hat{\mathcal{R}}(f)$$

1.2. Empirical Risk Minimization

- 1. For a chosen set of function classes  $\mathcal{F}$  minimize the empirical risk/loss:

$$\hat{f} \in \arg \min_{f \in \mathcal{F}} \hat{\mathcal{R}} \left( f, \mathcal{Z}^{tr} \right) = \arg \min_{f \in \mathcal{F}} \frac{1}{n} \sum_{i=1}^n l \left( y_i, f(\boldsymbol{x}_i) \right)$$

- 2. Determine the best parameter  $\theta^*$  by using the validation set for evaluation:

$$\hat{\theta} \left( \mathcal{Z}^{val} \right) \in \arg \min_{\theta: \hat{f}_{\theta} \in \mathcal{F}_{\theta}} \hat{R} \left( \hat{f}_{\theta} \left( \mathcal{Z}^{tr} \right), \mathcal{Z}^{val} \right)$$

- 3. Use the tests set in order to test the model:

$$\hat{\mathcal{R}} \left( \hat{f}_{\hat{\theta} \left( \mathcal{Z}^{val} \right)} \left( \mathcal{Z}^{tr} \right), \mathcal{Z}^{test} \right)$$

**Note: overfitting to the validation set**

Tuning the configuration/hyperparameters of the model based on its performance on the validation set can result in overfitting to the validation set, even though your model is never directly trained on it  $\Rightarrow$  split the data into a test and training and validation set.

2. Cross Validation

**Definition 3.9 Cross Validation:** Is a model validation/assessment techniques for assessing how the results of a statistical analysis (model) will generalize to an independent data set.

2.1. Validation Set Approach

**Definition 3.10 Hold out/Validation Set:**

2.2. Leave-One-Out Cross Validation (LOOCV)

2.3. K-Fold Cross Validation

# A Statistical Perspective

## 1. Information Theory

### 1.1. Information Content

**Definition 4.1 Information** (Claude Elwood Shannon): Information is the resolution of uncertainty.

#### Amount of Information

The information gained of by the realization of a coin tossed  $n$ -times should equal to the sum of the information of tossing a coin once  $n$ -times:

$$I(\mathbf{p}_1 \cdots \mathbf{p}_0 \cdots \mathbf{p}_1) = I(\mathbf{p}_1) + I(\mathbf{p}_0) + \cdots + I(\mathbf{p}_n)$$

$\Rightarrow$  can use the logarithm to satisfy this

**Definition 4.2 Surprise/Self-Information/-Content:** Is a measure of the information of a realization  $x$  of a random variable  $X \sim \mathbf{p}$ :

$$I_X(x) = \log\left(\frac{1}{\mathbf{p}(X=x)}\right) = -\log \mathbf{p}(X=x) \quad (4.1)$$

**Corollary 4.1 Units of the Shannon Entropy:**

The Shannon entropy can be defined for different logarithms

	log	units
$\cong$ units:	Base 2	Bits/Shannons
	Natural	Nats
	Base 10	Dits/Bans

**Explanation 4.1.** An uncertain event is much more informative than an expected/certain event:

$$\text{surprise/inf. content} = \begin{cases} \text{big} & \text{if } \mathbf{p}_X(x) \text{ unlikely} \\ \text{small} & \text{if } \mathbf{p}_X(x) \text{ likely} \end{cases}$$

Information content deals with a single event if we want to quantify the amount of uncertainty/information of an probability distribution we need to take the expectation over the information content<sup>[def. 4.2]</sup>:

**Definition 4.3 Shannon Entropy** example 4.3: Is the expected amount of information of a random variable  $X \sim \mathbf{p}$ :

$$\begin{aligned} H(\mathbf{p}) &= \mathbb{E}_X[I_X(x)] = \mathbb{E}_X\left[\log \frac{1}{\mathbf{p}_X(x)}\right] = -\mathbb{E}_X[\log \mathbf{p}_X(x)] \\ &= -\sum_{i=1}^n \mathbf{p}(x_i) \log \mathbf{p}(x_i) \end{aligned} \quad (4.2)$$

**Definition 4.4 Differential/Continuous entropy:** Is the continuous version of the Shannon entropy<sup>[def. 4.3]</sup>:

$$H(\mathbf{p}) = \int_{x \sim \mathbf{p}} -f(x) \log f(x) \, dx \quad (4.3)$$

#### Notes

The Shannon entropy is maximized for uniform distributions

### 1.2. Cross Entropy

**Definition 4.5 Cross Entropy** proof 4: Lets say a model follows a true distribution  $X \sim \mathbf{p}$  but we model  $X$  as with a different distribution  $X \sim \mathbf{q}$ . The cross entropy between  $\mathbf{p}$  and  $\mathbf{q}$  measure the average amount of information/bits needed to model an outcome  $x \sim \mathbf{p}$  with  $X$ :

$$H(\mathbf{p}, \mathbf{q}) = \mathbb{E}_{x \sim \mathbf{p}} \left[ \log \left( \frac{1}{\mathbf{q}(x)} \right) \right] = -\mathbb{E}_{x \sim \mathbf{p}} [\log \mathbf{q}(x)] \quad (4.4)$$

$$= H(\mathbf{p}) + D_{\text{KL}}(\mathbf{p} \parallel \mathbf{q}) \quad (4.5)$$

**Corollary 4.2 Kullback-Leibler Divergence:**  $D_{\text{KL}}(\mathbf{p} \parallel \mathbf{q})$  measures the extra price (bits) we need to pay for using  $\mathbf{q}$ .

### 1.3. Kullback-Leibler (KL) divergence

If we want to measure how different two distributions  $\mathbf{q}$  and  $\mathbf{p}$  over the same random variable  $X$  are we can define another measure.

#### Definition 4.6

**Kullback–Leibler divergence.** examples 4.4 and 4.7 /**Relative Entropy from  $\mathbf{p}$  to  $\mathbf{q}$ :** Given two probability distributions  $\mathbf{p}, \mathbf{q}$  of a random variable  $X$ . The Kullback–Leibler divergence is defined to be:

$$D_{\text{KL}}(\mathbf{p} \parallel \mathbf{q}) = \mathbb{E}_{x \sim \mathbf{p}} \left[ \log \frac{\mathbf{p}(x)}{\mathbf{q}(x)} \right] = \mathbb{E}_{x \sim \mathbf{p}} [\log \mathbf{p}(x) - \log \mathbf{q}(x)] \quad (4.6)$$

and measures how far away a distribution  $\mathbf{q}$  is from a another distribution  $\mathbf{p}$ .

#### Explanation 4.2.

- $\mathbf{p}$  decides where we put the mass if  $\mathbf{p}(x)$  is zero we do not care about  $\mathbf{q}(x)$ .
- $\mathbf{p}(x)/\mathbf{q}(x)$  determines how big the difference between the distributions is.

#### Intuition

The KL-divergence helps us to measure just how much information we lose when we choose an approximation.

**Property 4.1 Non-Symmetric:**

$$D_{\text{KL}}(\mathbf{p} \parallel \mathbf{q}) \neq D_{\text{KL}}(\mathbf{q} \parallel \mathbf{p}) \quad \forall \mathbf{p}, \mathbf{q} \quad (4.7)$$

#### Property 4.2:

$$D_{\text{KL}}(\mathbf{p} \parallel \mathbf{q}) \geq 0 \quad (4.8)$$

$$D_{\text{KL}}(\mathbf{p} \parallel \mathbf{q}) = 0 \iff \mathbf{p}(x) = \mathbf{q}(x) \forall x \in \mathcal{X} \quad (4.9)$$

#### Note

The KL-divergence is not a real distance measure as  $\text{KL}(\mathbf{p} \parallel \mathbf{q}) \neq \text{KL}(\mathbf{q} \parallel \mathbf{p})$

## 2. Supervised Learning

**Recall:** goal of supervised learning

**Given:** training data:

$$\mathcal{D} = \{(\mathbf{x}_1, y_1), \dots, (\mathbf{x}_n, y_n)\} \subseteq \mathcal{X} \times \mathcal{Y}$$

**find** a hypothesis  $h: \mathcal{X} \rightarrow \mathcal{Y}$  e.g.

- Linear Regression:**  $h(\mathbf{x}) = \mathbf{w}^\top \mathbf{x}$
- Linear Classification:**  $h(\mathbf{x}) = \text{sing}(\mathbf{w}^\top \mathbf{x})$
- Kernel Regression:**  $h(\mathbf{x}) = \sum_{i=1}^n \alpha_i \mathbf{k}(\mathbf{x}_i, \mathbf{x})$

- Neural Networks** (single hidden layer):  $h(\mathbf{x}) = \sum_{i=1}^n \mathbf{w}'_i \phi(\mathbf{w}^\top_i \mathbf{x})$

**s.t.** we minimize prediction error/empirical risk<sup>[def. 4.11]</sup>.

#### Fundamental assumption

The data is generated *i.i.d.* from some unknown probability distribution:

$$(\mathbf{x}_i, y_i) \sim \mathbf{p}_{\mathcal{X}, \mathcal{Y}}(\mathbf{x}_i, y_i)$$

#### Note

The distribution  $\mathbf{p}_{\mathcal{X}, \mathcal{Y}}$  is dedicated by nature and may be highly complex (not smooth, multimodal, ...).

### 2.1. Generalization Error

#### Definition 4.7

**Generalization/Prediction Error (Risk):** Is defined as the expected value of a loss function  $l$  of a given predictor  $h$ , for data drawn from a distribution  $\mathbf{p}_{\mathcal{X}, \mathcal{Y}}$ .

$$\begin{aligned} R_{\mathbf{p}}(h) &= \mathbb{E}_{(\mathbf{x}, y) \sim \mathbf{p}} [l(y; h(\mathbf{x}))] = \int_{\mathcal{D}} \mathbf{p}(\mathbf{x}, y) l(y; h(\mathbf{x})) \, d\mathbf{x} \, dy \\ &= \int_{\mathcal{X}} \int_{\mathcal{Y}} \mathbf{p}(\mathbf{x}, y) l(y, h(\mathbf{x})) \, d\mathbf{x} \, dy \\ &\stackrel{??}{=} \int_{\mathcal{X}} \int_{\mathcal{Y}} l(y, h(\mathbf{x})) \mathbf{p}(y|\mathbf{x}) \mathbf{p}(\mathbf{x}) \, d\mathbf{x} \, dy \end{aligned} \quad (4.10)$$

#### Interpretation

Is a measure of how accurately an algorithm is able to predict outcome values for future/unseen/test data.

**Definition 4.8 Expected Conditional Risk:** If we only know a certain  $\mathbf{x}$  but not the distribution of those measurements ( $\mathbf{x} \sim \mathbf{p}_{\mathcal{X}}(\mathbf{x})$ ), we can still calculate the expected risk given/conditioned on the known measurement  $\mathbf{x}$ :

$$\mathcal{R}_{\mathbf{p}}(h, \mathbf{x}) = \int_{\mathcal{Y}} l(y, h(\mathbf{x})) \mathbf{p}(y|\mathbf{x}) \, dy$$

**Note:** [def. 4.7]  $\iff$  [def. 4.8]

$$R_{\mathbf{p}}(h) = \mathbb{E}_{\mathbf{x} \sim \mathbf{p}} [R_{\mathbf{p}}(h, \mathbf{x})] = \int_{\mathcal{X}} \mathbf{p}(\mathbf{x}) R_{\mathbf{p}}(h, \mathbf{x}) \, d\mathbf{x} \quad (4.11)$$

**Definition 4.9 Expected Risk Minimizer (TRM)  $h^*$ :** Is the model  $h$  that minimizes the total expected risk:

$$h^* \in \arg \min_{h \in \mathcal{C}} \mathcal{R}(h) \quad (4.12)$$

#### Problem

In practice we do neither know the distribution  $\mathbf{p}_{\mathcal{X}, \mathcal{Y}}(\mathbf{x}, y)$ , nor  $\mathbf{p}_{\mathcal{X}}(\mathbf{x})$  or  $\mathbf{p}_{\mathcal{Y}|\mathcal{X}}(y|\mathbf{x})$  (otherwise we would already know the solution).

**But:** even though we do not know the distribution of  $\mathbf{p}_{\mathcal{X}, \mathcal{Y}}(\mathbf{x}, y)$  we can still sample from it in order to define an empirical risk.

### 2.2. Empirical Risk

**Definition 4.10 Empirical Risk:** Is the the average of a loss function of an estimator  $h$  over a finite set of data  $\mathcal{D} = \{\mathbf{x}_i, y_i\}_{i=1}^n$  drawn from  $\mathbf{p}_{\mathcal{X}, \mathcal{Y}}(\mathbf{x}, y)$ :

$$\hat{\mathcal{R}}_n(h) = \frac{1}{n} \sum_{i=1}^n l(h(\mathbf{x}_i), y_i)$$

#### Note

- $\hat{\mathcal{R}}_n(f) \neq \mathbb{E}_{\mathcal{X}, \mathcal{Y}}[l(f(\mathbf{x}), y)]$ .
- We hope that  $\lim_{n \rightarrow \infty} \hat{\mathcal{R}}_n(f) = \mathcal{R}(f)$ .

**Definition 4.11 Empirical Risk Minimizer (ERM)  $\hat{h}$ :** Is the model  $h$  that minimizes the total empirical risk:

$$\hat{h} \in \arg \min_{h \in \mathcal{C}} \hat{\mathcal{R}}(h) \quad (4.13)$$

#### 2.2.1. Bayes Optimal Predictor

##### Objective

**Given** data generated *i.i.d.* from an distribution

$\mathbf{p}_{\mathcal{X}, \mathcal{Y}}(\mathbf{x}_i, y_i)$ .

**Goal:** find the function/predictor  $h: \mathcal{X} \rightarrow \mathcal{Y}$  that minimizes the expected risk<sup>[def. 4.7]</sup> i.e. we want to find the expected risk minimizer<sup>([def. 4.9])</sup>.

#### Definition 4.12

**Bayes' optimal predictor for the L2-Loss:**

**Assuming:** i.i.d. generated data by  $(\mathbf{x}_i, y_i) \sim \mathbf{p}(\mathcal{X}, \mathcal{Y})$ .

**Considering:** the least squares risk:

$$R_{\mathbf{p}}(h) = \mathbb{E}_{(\mathbf{x}, y) \sim \mathbf{p}} [(y - h(\mathbf{x}))^2]$$

The best hypothesis/predictor  $h^*$  minimizing  $R(h)$  is given by **conditional mean/expectation** of the data:

$$h^*(\mathbf{x}) = \mathbb{E}[Y|\mathbf{X} = \mathbf{x}] \quad (4.14)$$

see

*Proof.* proof: defn: bayesOptPredictor

#### Notes

- The optimal predictor may not be unique as even for a fixed  $\mathbf{X}$  we may sample different  $Y$ , that is if we observe a  $\mathbf{x}$  multiple times we may still get different  $y$  values.
- Our model/prediction is unique, can only predict a specific  $y$ .  
**Hence** even if our model fits exactly the data generating process  $\mathbf{X} = \mathbf{x}$  we may still obtain different  $y$ 's because due to random/independent measurement noise/errors that the optimal bayes predictor still makes.

### 2.3. How to make use of this in Practice

#### In Practice

**Problem:** we do not know the real distribution  $\mathbf{p}_{\mathcal{Y}|\mathcal{X}}(y|\mathbf{x})$ , which we need in order to find the bayes optimal predictor according to eq. (4.14).

**Idea:**

- Use artificial data/density estimator  $\hat{\mathbf{p}}(\mathcal{Y}|\mathcal{X})$  in order to estimate  $\mathbb{E}[\mathcal{Y}|\mathcal{X} = \mathbf{x}]$
- Predict a test point  $\mathbf{x}$  by:  
$$\hat{y} = \hat{\mathbb{E}}[\mathcal{Y}|\mathcal{X} = \mathbf{x}] = \int \hat{\mathbf{p}}(y|\mathbf{X} = \mathbf{x}) y \, dy$$

**Common approach:**  $\mathbf{p}(\mathcal{X}, \mathcal{Y})$  may be some very complex (non-smooth, ...) distribution  $\Rightarrow$  need to make some assumptions in order to approximate  $\mathbf{p}(\mathcal{X}, \mathcal{Y})$  by  $\hat{\mathbf{p}}(\mathcal{X}, \mathcal{Y})$  **Idea:** choose parametric form  $\hat{\mathbf{p}}(Y|\mathbf{X}, \theta) = \hat{\mathbf{p}}_{\theta}(Y|\mathbf{X})$  and then optimize the parameter  $\theta$  which results in the so called maximum likelihood estimation section 1.

**Definition 4.13 Statistical Inference:** Goal of Inference

- What is a good guess of the parameters of my model?
- How do I quantify my uncertainty in the guess?

### 3. Estimators

**Definition 4.14 (Sample) Statistic:** A statistic is a measurable function  $f$  that assigns a **single** value  $F$  to a sample of random variables:  
$$\mathbf{X} = \{X_1, \dots, X_n\}$$
$$f: \mathbb{R}^n \mapsto \mathbb{R} \quad F = f(X_1, \dots, X_n)$$

E.g.  $F$  could be the mean, variance, ...

#### Note

The function itself is independent of the sample's distribution; that is, the function can be stated before realization of the data.

**Definition 4.15 Statistical/Population Parameter:**

Is a parameter defining a family of probability distributions see example 4.1

**Definition 4.16 (Point) Estimator  $\hat{\theta} = \hat{\theta}(\mathbf{X})$ :**

**Given:**  $n$ -samples  $\mathbf{x}_1, \dots, \mathbf{x}_n \sim \mathbf{X}$  an estimator  
$$\hat{\theta} = \hat{h}(\mathbf{x}_1, \dots, \mathbf{x}_n) \quad (4.15)$$

is a statistic/random variable used to estimate a true (population) parameter  $\theta$ <sup>[def. 4.15]</sup> see also example 4.2.

#### Note

The other kind of estimators are interval estimators which do not calculate a statistic **but** an interval of plausible values of an unknown population parameter  $\theta$ .

The most prevalent forms of interval estimation are:

- Confidence intervals (frequentist method).
- Credible intervals (Bayesian method).

### 4. Proofs

*Proof.* [def. 4.5]

$$\begin{aligned} \mathbb{E}_{\mathbf{x} \sim \mathbf{q}} \left[ \log \left( \frac{1}{\mathbf{p}(x)} \right) \right] &= \mathbb{E}_{\mathbf{x} \sim \mathbf{q}} \left[ \log \left( \frac{\mathbf{q}(x)}{\mathbf{p}(x)} \right) + \log \left( \frac{1}{\mathbf{q}(x)} \right) \right] \\ &= H(\mathbf{p}) + D_{\text{KL}}(\mathbf{p} \parallel \mathbf{q}) \end{aligned}$$

□

*Proof.* <sup>[def. 4.12]</sup>:

$$\begin{aligned}
\min_h R(h) &= \min_h \mathbb{E}_{(\mathbf{x}, y) \sim \mathbf{p}} [(y - h(\mathbf{x}))^2] \\
&\stackrel{??}{=} \min_h \mathbb{E}_{\mathbf{x} \sim \mathbf{p}} \mathbb{E}_{y \sim \mathbf{p}_{Y|\mathbf{x}}} \left[ (y - h(\mathbf{x}))^2 \mid \mathbf{x} \right] \\
&\stackrel{\heartsuit}{=} \mathbb{E}_{\mathbf{x} \sim \mathbf{p}} \mathbb{E}_{y \sim \mathbf{p}_{Y|\mathbf{x}}} \left[ \underbrace{\min_h (y - h(\mathbf{x}))^2}_{\mathcal{R}_Y(h, \mathbf{x})} \mid \mathbf{x} \right] \quad (\text{def. 4.8})
\end{aligned}$$

Now let's minimize the conditional executed risk:

$$\begin{aligned}
h^*(\mathbf{x}) &= \arg \min_h \mathbb{E}_{y \sim \mathbf{p}_{Y|\mathbf{x}}} \left[ (y - h(\mathbf{x}))^2 \mid \mathbf{x} \right] \quad (4.16) \\
0 &\stackrel{!}{=} \frac{d}{dh^*} \mathcal{R}_Y(h^*, \mathbf{x}) = \frac{d}{dh^*} \int (y - h^*)^2 \mathbf{p}(y \mid \mathbf{x}) dy \\
&= \int \frac{d}{dh^*} (y - h^*)^2 \mathbf{p}(y \mid \mathbf{x}) dy = \int 2(y - h^*) \mathbf{p}(y \mid \mathbf{x}) dy \\
&= -2h^* \underbrace{\int \mathbf{p}(y \mid \mathbf{x}) dy}_{=1} + 2 \underbrace{\int y \mathbf{p}(y \mid \mathbf{x}) dy}_{\mathbb{E}_Y[Y \mid X = \mathbf{x}]}
\end{aligned}$$

**Notes:**  $\heartsuit$

Since we can pick  $h(\mathbf{x}_i)$  independently from  $h(\mathbf{x}_j)$ .

**Note**

$$\begin{aligned}
\mathbb{E}[X] \mathbb{E}[Y \mid X] &= \int_X \mathbf{p}_X(x) dx \int_Y \mathbf{p}(y \mid x) dy \\
&= \int_X \int_Y \mathbf{p}_X(x) \mathbf{p}(y \mid x) xy dx dy = \mathbb{E}[X, Y]
\end{aligned}$$

*Proof.* example 4.4

$$\begin{aligned}
\text{KL}(\mathbf{p} \parallel \mathbf{q}) &= \mathbb{E}_{\mathbf{p}} [\log(\mathbf{p}) - \log(\mathbf{q})] \\
&= \mathbb{E}_{\mathbf{p}} \left[ \frac{1}{2} \log \frac{|\Sigma_{\mathbf{q}}|}{|\Sigma_{\mathbf{p}}|} - \frac{1}{2} (\mathbf{x} - \boldsymbol{\mu}_{\mathbf{p}})^{\mathsf{T}} \Sigma_{\mathbf{p}}^{-1} (\mathbf{x} - \boldsymbol{\mu}_{\mathbf{p}}) \right. \\
&\quad \left. + \frac{1}{2} (\mathbf{x} - \boldsymbol{\mu}_{\mathbf{q}})^{\mathsf{T}} \Sigma_{\mathbf{q}}^{-1} (\mathbf{x} - \boldsymbol{\mu}_{\mathbf{q}}) \right] \\
&= \frac{1}{2} \mathbb{E}_{\mathbf{p}} \left[ \log \frac{|\Sigma_{\mathbf{q}}|}{|\Sigma_{\mathbf{p}}|} \right] - \frac{1}{2} \mathbb{E}_{\mathbf{p}} \left[ (\mathbf{x} - \boldsymbol{\mu}_{\mathbf{p}})^{\mathsf{T}} \Sigma_{\mathbf{p}}^{-1} (\mathbf{x} - \boldsymbol{\mu}_{\mathbf{p}}) \right] \\
&\quad + \frac{1}{2} \mathbb{E}_{\mathbf{p}} \left[ (\mathbf{x} - \boldsymbol{\mu}_{\mathbf{q}})^{\mathsf{T}} \Sigma_{\mathbf{q}}^{-1} (\mathbf{x} - \boldsymbol{\mu}_{\mathbf{q}}) \right] \\
&= \frac{1}{2} \log \frac{|\Sigma_{\mathbf{q}}|}{|\Sigma_{\mathbf{p}}|} - \frac{1}{2} \mathbb{E}_{\mathbf{p}} \left[ (\mathbf{x} - \boldsymbol{\mu}_{\mathbf{p}})^{\mathsf{T}} \Sigma_{\mathbf{p}}^{-1} (\mathbf{x} - \boldsymbol{\mu}_{\mathbf{p}}) \right] \\
&\quad + \frac{1}{2} \mathbb{E}_{\mathbf{p}} \left[ (\mathbf{x} - \boldsymbol{\mu}_{\mathbf{q}})^{\mathsf{T}} \Sigma_{\mathbf{q}}^{-1} (\mathbf{x} - \boldsymbol{\mu}_{\mathbf{q}}) \right]
\end{aligned}$$

$$\begin{aligned}
\underbrace{\mathbb{E}_{\mathbf{p}}[a]}_{\text{eq. (16.15)}} &\stackrel{\text{tr}(\mathbb{R}) = \mathbb{R}}{=} \mathbb{E}_{\mathbf{p}} \left[ \text{tr} \left\{ (\mathbf{x} - \boldsymbol{\mu}_{\mathbf{p}})^{\mathsf{T}} \Sigma_{\mathbf{p}}^{-1} (\mathbf{x} - \boldsymbol{\mu}_{\mathbf{p}}) \right\} \right] \\
&= \mathbb{E}_{\mathbf{p}} \left[ \text{tr} \left\{ (\mathbf{x} - \boldsymbol{\mu}_{\mathbf{p}}) (\mathbf{x} - \boldsymbol{\mu}_{\mathbf{p}})^{\mathsf{T}} \Sigma_{\mathbf{p}}^{-1} \right\} \right] \\
&= \mathbb{E}_{\mathbf{p}} \left[ \text{tr} \left\{ \Sigma_{\mathbf{p}} \Sigma_{\mathbf{p}}^{-1} \right\} \right] \\
&\stackrel{\text{eq. (16.15)}}{=} \mathbb{E}_{\mathbf{p}} [\text{tr} \{I_d\}] = \mathbb{E}_{\mathbf{p}} [d] = d \\
\underbrace{\mathbb{E}_{\mathbf{p}}[b]}_{\text{eq. (21.56)}} &\stackrel{!}{=} (\boldsymbol{\mu}_{\mathbf{p}} - \boldsymbol{\mu}_{\mathbf{q}})^{\mathsf{T}} \Sigma_{\mathbf{q}}^{-1} (\boldsymbol{\mu}_{\mathbf{p}} - \boldsymbol{\mu}_{\mathbf{q}}) + \text{tr} \left\{ \Sigma_{\mathbf{q}}^{-1} \Sigma_{\mathbf{p}} \right\}
\end{aligned}$$

## 5. Examples

**Example 4.1 :** Normal distribution has two population parameters: the mean  $\boldsymbol{\mu}$  and the variance  $\sigma^2$ .

**Example 4.2 Various kind of estimators:**

- Best linear unbiased estimator (**BLUE**).
- Minimum-variance mean-unbiased estimator (**MVUE**): minimizes the risk (expected loss) of the squared-error loss-function.
- Minimum mean squared error (**MMSE**).
- Maximum likelihood estimator (**MLE**): is given by the least squares solution (minimum squared error), assuming that the noise is i.i.d. Gaussian with constant variance and will be considered in the next section.

**Example 4.3 Entropy of a Gaussian:**

$$\begin{aligned}
H(\mathcal{N}(\boldsymbol{\mu}, \Sigma)) &= \frac{1}{2} \ln |2\pi e \Sigma| \\
&\stackrel{\Sigma = \text{diag}(\sigma_1^2, \dots, \sigma_d^2)}{=} \frac{1}{2} \ln |2\pi e| + \frac{1}{2} \sum_{i=1}^d \ln \sigma_i^2
\end{aligned}$$

**Example 4.4** proof 4

**KL Divergence of Gaussians:**

Given two Gaussian distributions:

$$\mathbf{p} = \mathcal{N}(\boldsymbol{\mu}_{\mathbf{p}}, \Sigma_{\mathbf{p}}) \quad \mathbf{q} = \mathcal{N}(\boldsymbol{\mu}_{\mathbf{q}}, \Sigma_{\mathbf{q}}) \quad \text{it holds}$$

$$\begin{aligned}
D_{\text{KL}}(\mathbf{p} \parallel \mathbf{q}) &= \\
&= \frac{\text{tr} \left( \Sigma_{\mathbf{q}}^{-1} \Sigma_{\mathbf{p}} \right) + (\boldsymbol{\mu}_{\mathbf{q}} - \boldsymbol{\mu}_{\mathbf{p}})^{\mathsf{T}} \Sigma_{\mathbf{q}}^{-1} (\boldsymbol{\mu}_{\mathbf{q}} - \boldsymbol{\mu}_{\mathbf{p}}) - d + \ln \left( \frac{|\Sigma_{\mathbf{q}}|}{|\Sigma_{\mathbf{p}}|} \right)}{2}
\end{aligned}$$

**Example 4.5 KL Divergence of Scalar Gaussians:**

$$\begin{aligned}
\theta \sim q(\theta \mid \boldsymbol{\lambda}) &= \mathcal{N}(\boldsymbol{\mu}_{\mathbf{q}}, \sigma_{\mathbf{q}}^2) \quad \boldsymbol{\lambda} = [\boldsymbol{\mu}_{\mathbf{q}} \quad \sigma_{\mathbf{q}}] \\
\mathbf{p} &= \mathcal{N}(\boldsymbol{\mu}_{\mathbf{p}}, \sigma_{\mathbf{p}}^2) \\
D_{\text{KL}}(\mathbf{p} \parallel \mathbf{q}) &= \frac{1}{2} \left( \frac{\sigma_{\mathbf{p}}^2}{\sigma_{\mathbf{q}}^2} (\boldsymbol{\mu}_{\mathbf{q}} - \boldsymbol{\mu}_{\mathbf{p}})^2 \sigma_{\mathbf{q}}^{-2} - 1 + \log \left( \frac{\sigma_{\mathbf{q}}^2}{\sigma_{\mathbf{p}}^2} \right) \right)
\end{aligned}$$

**Example 4.6 KL Divergence of Diag. Gaussians:**

$$\begin{aligned}
\theta \sim q(\theta \mid \boldsymbol{\lambda}) &= \mathcal{N}(\boldsymbol{\mu}_{\mathbf{q}}, \text{diag}(\sigma_1^2, \dots, \sigma_d^2)) \quad \boldsymbol{\lambda} = [\boldsymbol{\mu}_{1:d} \quad \sigma_{1:d}] \\
\mathbf{p} &= \mathcal{N}(\boldsymbol{\mu}_{\mathbf{p}}, \text{diag}(\sigma_1^2, \dots, \sigma_d^2))
\end{aligned}$$

**Example 4.7 KL Divergence of Gaussians:**

$$\mathbf{p} = \mathcal{N}(\boldsymbol{\mu}_{\mathbf{p}}, \text{diag}(\sigma_1^2, \dots, \sigma_d^2)) \quad \mathbf{q} = \mathcal{N}(\mathbf{0}, \mathbf{I}) \quad \text{it holds}$$

$$D_{\text{KL}}(\mathbf{p} \parallel \mathbf{q}) = \frac{1}{2} \sum_{i=1}^d \left( \sigma_i^2 + \mu_i^2 - 1 - \ln \sigma_i^2 \right)$$

# Model Parameter Estimation

## 1. Maximum Likelihood Estimation

### 1.1. Likelihood Function

Is a method for estimating the parameters  $\theta$  of a model that agree best with observed data  $\{x_1, \dots, x_n\}$ . Let:  $\theta = (\theta_1 \dots \theta_k)^\top \in \Theta \subset \mathbb{R}^k$  vector of unknown model parameters.

**Consider:** a probability density/mass function  $f_X(x; \theta)$

**Definition 5.1 Likelihood Function**  $\mathcal{L}_n : \Theta \times \mathbb{R}^n \mapsto \mathbb{R}_+$ : Let  $\mathbf{X} = \{x_i\}_{i=1}^n$  be a random sample of i.i.d. data points drawn from an unknown probability distribution  $x_i \sim p_X$ . The likelihood function gives the likelihood/probability of the joint probability of the data  $\{x_1, \dots, x_n\}$  given a fixed set of model parameters  $\theta$ :

$$\mathcal{L}_n(\theta|\mathbf{X}) = \mathcal{L}_n(\theta; \mathbf{X}) = f(\mathbf{X}|\theta) = f(\mathbf{X}; \theta) \quad (5.1)$$

Figure 1: Possible Likelihood function in pink. Overlaid: possible candidate functions for Gaussian model explaining the observations.

#### Likelihood function is not a pdf

The likelihood function by default not a probability density function and may not even be differentiable. However if it is, then it may be normalized to one.

**Corollary 5.1 i.i.d. data:** If the n-data points of our sample are i.i.d. then the likelihood function can be decomposed into a product of n-terms:

Figure 2: Bottom: probability distributions of the different data points  $x_i$  given a fixed  $\theta$  for a Gaussian distribution. Top: joint probability distribution of the i.i.d. data points  $\{x_i\}_{i=1}^n$  given a fixed  $\theta$

$$f(x_1, \dots, x_n | \theta) \stackrel{\text{i.i.d.}}{=} \prod_{i=1}^n f(x_i | \theta)$$

#### Notation

- The probability density  $f(\mathbf{X}|\theta)$  is considered for a fixed  $\theta$  and thus as a function of the samples.
- The likelihood function on the other hand is considered as a function over parameter values  $\theta$  for a fixed sample  $\{x_i\}_{i=1}^n$  and thus written as  $\mathcal{L}_n(\theta|\mathbf{X})$ .
- Often the colon symbol ; is written instead of the *is given* symbol | in order to indicate that  $\theta$  resp.  $\mathbf{X}$  is a parameter and not a random variable.

### 1.2. Maximum Likelihood Estimation (MLE)

Let  $f_\theta(x)$  be the probability of an i.i.d. sample  $x$  for a given model.

Goal: find  $\theta$  of a given model that maximizes the joint probability/likelihood of the observed data  $\{x_1, \dots, x_n\}$ ?  $\iff$  maximum likelihood estimator  $\theta^*$ .

**Definition 5.2 Log Likelihood Function**  $l_n : \Theta \times \mathbb{R}^n \mapsto \mathbb{R}$ :

$$l_n(\theta|\mathbf{X}) = \log \mathcal{L}_n(\theta|\mathbf{X}) = \log f(\mathbf{X}|\theta) \quad (5.2)$$

**Corollary 5.2 i.i.d. data:** Differentiating the product of n-terms with the help of the chain rule leads often to complex terms. As a result one usually prefers maximizing the log (especially for exponential terms), as it does not change the *argmaxeq.* (13.51):

$$\log f(x_1, \dots, x_n | \theta) \stackrel{\text{i.i.d.}}{=} \log \left( \prod_{i=1}^n f(x_i | \theta) \right) = \sum_{i=1}^n \log f(x_i | \theta)$$

**Definition 5.3 Maximum Likelihood Estimator**  $\theta^*$ : Is the estimator  $\theta^* \in \Theta$  that maximizes the likelihood of the model/predictor:

$$\theta^* = \arg \max_{\theta \in \Theta} \mathcal{L}_n(\theta; \mathbf{x}) \quad \text{or} \quad \theta^* = \arg \max_{\theta \in \Theta} l_n(\theta; \mathbf{x}) \quad (5.3)$$

### 1.3. Maximization vs. Minimization

For optimization problems we minimize by convention. The logarithm is a concave function<sup>[def. 13.21]</sup>  $\cap$ , thus if we calculate the extremal point we will obtain a maximum. If we want to calculate a minimum instead (i.e. in order to be compatible with some computer algorithm) we can convert the function into a convex function<sup>section 3</sup>  $\cup$  by multiplying it by minus one and consider it as a loss function instead of a likelihood.

**Definition 5.4 Negative Log-likelihood**  $-l_n(\theta|\mathbf{X})$ :

$$\theta^* = \arg \max_{\theta \in \Theta} l_n(\theta|\mathbf{X}) = \arg \min_{\theta \in \Theta} -l_n(\theta|\mathbf{X}) \quad (5.4)$$

### 1.4. Conditional Maximum Likelihood Estimation

Maximum likelihood estimation can also be used for conditional distributions.

Assume the labels  $y_i$  are drawn i.i.d. from an unknown true conditional probability distribution  $f_{Y|X}$  and we are given a data set  $\mathbf{Z} = \{(x_i, y_i) \in \mathbb{R}^d \times \mathbb{R}\}_{i=1}^n$ .

Now we want to find the parameters  $\theta = (\theta_1 \dots \theta_k)^\top \in \Theta \subset \mathbb{R}^k$  of a hypothesis  $\hat{f}_{Y|X}$  that agree best with the given data  $\mathbf{Z}$ .

#### Note

For simplicity we omit the hat of our model  $\hat{f}_{Y|X}$  and simply assume that our data is generated by some data generating probability distribution.

**Definition 5.5 Conditional (log) likelihood function:**

Models the likelihood of a model with parameters  $\theta$  given the data  $\mathbf{Z} = \{x_i, y_i\}_{i=1}^n$   
 $\mathcal{L}_n(\theta|Y, \mathbf{X}) = \mathcal{L}_n(\theta; Y, \mathbf{X}) = f(Y|\mathbf{X}, \theta) = f(Y|\mathbf{X}; \theta)$

### 2. Maximum a posteriori estimation (MAP)

#### Idea

We have seen (??), that trading/increasing a bit of bias can lead to a big reduction of variance of the generalization error. We also know that the least squares MLE is unbiased (??).

Thus the question arises if we can introduce a bit of bias into the MLE in turn of decreasing the variance?  
 $\Rightarrow$  use Bayes rule (??) to introduce a bias into our model via. a **Prior** distribution.

#### 2.1. Prior Distribution

**Definition 5.6 Prior (Distribution)**  $\pi(\theta) = p(\theta)$ :

**Assumes:** that the model parameters  $\theta$  are no longer constant but random variables distributed according to a prior distribution that models some prior belief/bias that we have about the model:

$$\theta \sim \pi(\theta) = p(\theta) \quad (5.5)$$

#### Notes

In this section we use the terms model parameters  $\theta$  and model as synonymous, as the model is fully described by its population parameters (<sup>[def. 4.15]</sup>  $\theta$ ).

**Corollary 5.3 The prior is independent of the data:** The prior  $p(\theta)$  models a prior belief/bias and is thus independent of the data  $\mathcal{D} = \{\mathcal{X}, \mathcal{Y}\}$ :

$$p(\theta|\mathbf{X}) = p(\theta) \quad (5.6)$$

**Definition 5.7 Hyperparameters**  $p_\lambda(\theta)$ : In most cases the prior distribution are parameterized that is the pdf  $\pi(\theta|\lambda)$  depends on a set of parameters  $\lambda$ . The parameters of the prior distribution, are called hyperparameters and are supplied due to believe/prior knowledge (and do not depend on the data) see example 5.1

### 2.2. Posterior Distribution

**Definition 5.8 Posterior Distribution**  $p(\theta|\text{data})$ : The posterior distribution  $p(\theta|\text{data})$  is a probability distribution that describes the relationship of a unknown parameter  $\theta$  a posterior/after observing evidence of a random quantity  $\mathbf{Z}$  that is in a relation with  $\theta$ :

$$p(\theta|\text{data}) = p(\theta|\mathbf{Z}) \quad (5.7)$$

#### Definition 5.9

**Posterior Distribution and Bayes Theorem:**

Using Bayes theorem 21.3 we can write the posterior distribution as a product of the *likelihood*<sup>[def. 5.1]</sup> weighted with our *prior*<sup>[def. 5.6]</sup> and normalized by the *evidence*  $\mathbf{Z} = \{\mathbf{X}, \mathbf{y}\}$  s.t. we obtain a real probability distribution:

$$p(\theta|\text{data}) = p(\theta|\mathbf{Z}) = \frac{p(\mathbf{Z}|\theta) \cdot p_\lambda(\theta)}{p(\mathbf{Z})} \quad (5.8)$$

$$\text{Posterior} = \frac{\text{Likelihood} \cdot \text{Prior}}{\text{Normalization}} \quad (5.9)$$

$$p(\theta|\mathbf{X}, \mathbf{y}) = \frac{p(\mathbf{y}|\theta, \mathbf{X}) \cdot p_\lambda(\theta)}{p(\mathbf{y}|\mathbf{X})} \quad (5.10)$$

see proof section 3

#### 2.2.1. Maximization – MAP

We do not care about the full posterior probability distribution as in Bayesian Inference (section 9). We only want to find a point estimator ??  $\theta^*$  that maximizes the posterior distribution.

#### 2.2.2. Maximization

##### Definition 5.10

**Maximum a-Posteriori Estimates (MAP):**

Is model/parameters  $\theta$  that maximize the posterior probability distribution:

$$\theta_{\text{MAP}}^* = \arg \max_{\theta} p(\theta|\mathbf{X}, \mathbf{y}) \quad (5.11)$$

**Log-MAP estimator:**

$$\theta^* = \arg \max_{\theta} \{p(\theta|\mathbf{X}, \mathbf{y})\} \quad (5.12)$$

$$= \arg \max_{\theta} \left\{ \frac{p(\mathbf{y}|\mathbf{X}, \theta) \cdot p_\lambda(\theta)}{p(\mathbf{y}|\mathbf{X})} \right\}$$

$$\stackrel{\text{eq. (13.48)}}{\propto} \arg \max_{\theta} \{p(\mathbf{y}|\theta, \mathbf{X}) \cdot p_\lambda(\theta)\}$$

**Corollary 5.4 Negative Log MAP:**

$$\theta^* = \arg \max_{\theta} \{p(\theta|\mathbf{X}, \mathbf{y})\} \quad (5.13)$$

$$= \arg \min_{\theta} - \log \overbrace{p(\theta)}^{\text{Prior}} - \log \overbrace{p(\mathbf{y}|\theta, \mathbf{X})}^{\text{Likelihood}} + \log \overbrace{p(\mathbf{y}|\mathbf{X})}^{\text{not depending on } \theta}$$

## 3. Proofs

*Proof. 5.10:*

$$\begin{aligned} p(\mathbf{X}, \mathbf{y}, \theta) &= \left\{ \frac{p(\theta|\mathbf{X}, \mathbf{y})p(\mathbf{X}, \mathbf{y})}{p(\mathbf{y}|\mathbf{X}, \theta)p(\mathbf{X}, \theta)} \right\} \\ \frac{p(\theta|\mathbf{X}, \mathbf{y})p(\mathbf{X}, \mathbf{y})}{p(\mathbf{y}|\mathbf{X}, \theta)p(\mathbf{X}, \theta)} &= \frac{p(\theta|\mathbf{X}, \mathbf{y})p(\mathbf{y}|\mathbf{X})p(\mathbf{X})}{p(\mathbf{y}|\mathbf{X}, \theta)p(\mathbf{X}, \theta)} \\ &= \frac{p(\mathbf{y}|\mathbf{X}, \theta)p(\theta|\mathbf{X})p(\mathbf{X})}{p(\mathbf{y}|\mathbf{X}, \theta)p(\mathbf{X}, \theta)} \\ &\stackrel{\text{eq. (5.6)}}{=} \frac{p(\mathbf{y}|\mathbf{X}, \theta)p(\theta)p(\mathbf{X})}{p(\mathbf{y}|\mathbf{X}, \theta)p(\mathbf{X}, \theta)} \\ &\Rightarrow \underline{p(\theta|\mathbf{X}, \mathbf{y})} = \frac{p(\mathbf{y}|\mathbf{X}, \theta)p(\theta)p(\mathbf{X})}{p(\mathbf{y}|\mathbf{X})p(\mathbf{X})} \end{aligned}$$

□

#### Note

This can also be derived by using the normal Bayes rule but additionally condition everything on  $\mathbf{X}$  (where the prior is independent on  $\mathbf{X}$ )

## 4. Examples

**Example 5.1 Hyperparameters Gaussian Prior:**

$$f_\lambda(\theta) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(\theta - \mu)^2}{2\sigma^2}\right)$$

with the hyperparameter  $\lambda = (\mu \ \sigma^2)^\top$ .

Regression

5. Linear/Ordinary Least Squares (OLS)

**Definition 5.11 Linear Regression:** Refers to regression that is linear w.r.t. to the parameter vector  $w$  (but not necessarily the data):

y = phi(x)^T w (5.14)

6. MLE with linear Model & Gaussian Noise
6.1. MLE for conditional linear Gaussians

Questions: what is P(Y|X) if we assume a relationship of the form: We can use the MLE to estimate the parameters theta\_R^k of a model/distribution h s.t.

y approx h(X; theta) iff y = h(X; theta) + epsilon
X: set of explicative variables. epsilon: noise/error term.

Lemma 5.1 : The conditional distribution D of Y given X is equivalent to the unconditional distribution of the noise epsilon:
P(Y|X) ~ D iff epsilon ~ D

Example: Conditional linear Gaussian

Assume: a linear model h(x) = w^T x and Gaussian noise epsilon ~ N(0, sigma^2)

With E[epsilon] = 0 and yi = w^T xi + epsilon, as well as ?? it follows:
y ~ P(Y = y|X = x, theta) ~ N(mu = h(x), sigma^2)
with: theta = (w^T sigma^T)^T in R^(n+1)

Hence Y is distributed as a linear transformation of the X variable plus some Gaussian noise epsilon: yi ~ N(w^T xi, sigma^2) => Conditional linear Gaussian.

if we consider an i.i.d. sample {yi, xi}^n\_{i=1}, the corresponding conditional (log-)likelihood is defined to be:

Ln(Y|X, theta) = P-hat(Y1, ..., Yn | x1, ..., xn, theta)
= product\_{i=1}^n P-hat(Y|X|xi, theta) = product\_{i=1}^n N(w^T xi, sigma^2)
= product\_{i=1}^n 1/(sqrt(sigma^2) \* 2 \* pi) \* exp(-((yi - w^T xi)^2)/(2 \* sigma^2))
= (sigma^2 \* 2 \* pi)^(-n/2) \* exp(-1/(2 \* sigma^2) \* sum\_{i=1}^n (yi - w^T xi)^2)

ln(Y|X, theta) = -n/2 \* ln(sigma^2) - n/2 \* ln(2 \* pi) - 1/(2 \* sigma^2) \* sum\_{i=1}^n (yi - w^T xi)^2

theta\* = arg max\_{w in R^d, sigma^2 in R+} ln(Y|X, theta)

partial ln(Y|X, theta) / partial theta = (partial ln(Y|X, theta) / partial w1, ..., partial ln(Y|X, theta) / partial wd, partial ln(Y|X, theta) / partial sigma^2)^T = (0d, 0)^T

partial ln(Y|X, theta) / partial w = 1/sigma^2 \* sum\_{i=1}^n xi (yi - w^T xi) = 0 in R^d
= (sum\_{i=1}^n xi xi^T) \* w = sum\_{i=1}^n xi yi

partial ln(Y|X, theta) / partial sigma^2 = -n/(2 \* sigma^2) + 1/(2 \* sigma^4) \* sum\_{i=1}^n (yi - w^T xi)^2 = 0

theta\* = (w\*, sigma\*^2) = ((sum\_{i=1}^n xi xi^T)^-1 \* (sum\_{i=1}^n xi yi), 1/n \* sum\_{i=1}^n (yi - w\*^T xi)^2) (5.15)

Note

- The mean mu of the normal distribution follows from: E[w^T xi + epsilon] = E[w^T xi] + E[epsilon] = w^T xi
const = 0
- The noise epsilon must have zero mean, otherwise it wouldn't be random anymore.
- The optimal function h\*(x) determines the mean mu.
- We can also minimize: theta\* = arg max\_theta P(Y|X, theta) = arg min\_theta -P-hat(Y|X, theta)

6.2. Conditional MLE equals Least Squares

Assuming that the noise is i.i.d. Gaussian with constant variance sigma, that is theta = (w, sigma^2)^T and considering the negative log likelihood in order to minimize arg max\_alpha = -arg min\_alpha:

-ln(w) = -product\_{i=1}^n ln(N(w^T xi, sigma^2)) = -n/2 \* ln(2 \* pi \* sigma^2) + sum\_{i=1}^n ((yi - w^T xi)^2)/(2 \* sigma^2)

arg max\_w ln(w) iff arg min\_w -ln(w)

arg min\_w 1/sigma^2 \* sum\_{i=1}^n (yi - w^T xi)^2 = arg min\_w sum\_{i=1}^n (yi - w^T xi)^2 (5.16)

Thus Least squares regression equals Conditional MLE with a linear model + Gaussian noise. Maximizing Likelihood iff Minimizing least squares

Corollary 5.5 : The Maximum Likelihood Estimate (MLE) for i.i.d. Gaussian noise (and general models) is given by the squared loss/Least squares solution, assuming that the variance is constant.

Heuristics for [def. 4.12]

Consider a sample {y1, ..., yn} ~ i.i.d. N(mu, sigma^2)

partial ln(y|x, theta) / partial mu = 1/sigma^2 \* sum\_{i=1}^n (yi - mu) = 0
partial ln(y|x, theta) / partial sigma^2 = -n/(2 \* sigma^2) + 1/(2 \* sigma^4) \* sum\_{i=1}^n (yi - mu)^2 = 0

theta\* = (mu\*, sigma\*^2) = ((1/n \* sum\_{i=1}^n yi), 1/n \* sum\_{i=1}^n (yi - yi\_bar)^2) (5.17)

So, the optimal MLE correspond to the empirical mean and the variance.

Note

partial w^T x / partial w = x

6.3. MLE for general conditional Gaussians

Suppose we do not just want to fit linear functions but a general class of models Hsp := {h : X -> R} e.g. neural networks, kernel functions,...

Given: data D = {(x1, y1), ..., (xn, yn)} The MLE for general models h and i.i.d. Gaussian noise:

h ~ P-hat(Y|X) (Y = y|X = x, theta) = N(y|h\*(x), sigma^2)

Is given by the least squares solution:

h\* = arg min\_{h in H} sum\_{i=1}^n (yi - h(xi))^2

E.g. for linear models H = {h(x) = w^T x with parameter w}

Other distributions

If we use other distributions instead of Gaussian noise, we obtain other loss functions e.g. L1-Norm for Poisson Distribution. => if we know something about the distribution of the data we know which loss function we should chose.

7. Gaussian MAP

Classification

8. Logistic Regression

Idea: in order to classify dichotomies we use a distribution that maps probabilities to a binary values 0/1 => Bernoulli Distribution [def. 23.22].

Problem: we need to convert/translate distance w^T x into probability in order to use a bernoulli distribution.

Idea: use a sigmoidal function to convert distances z := w^T x into probabilities => Logistic Function [def. 5.12].

8.1. Logistic Function

Definition 5.12 Sigmoid/Logistic Function:

sigma(z) = 1/(1 + e^-z) = 1/(1 + e^neg. dist. from deci. boundary) (5.18)

Explanation 5.1 (Sigmoid/Logistic Function).

sigma(z) = { 0 if -z large, 1 if z large, 0.5 if z = 0 }

8.2. Logistic Regression

Definition 5.13 Logistic Regression:

models the likelihood of the output y as a Bernoulli Distribution [def. 23.22] y ~ Bern(p), where the probability p is given by the Sigmoid function [def. 5.12] of a linear regression:

p(y|x, w) = Bern(sigma(w^T x)) = { 1/(1 + e^-w^T x) if y = +1, 1/(1 + e^w^T x) if y = -1 }
section 9: 1/(1 + exp(-y \* w^T x)) = sigma(-y \* w^T x) (5.19)

8.2.1. Maximum Likelihood Estimate

Definition 5.14 Logistic Loss l\_l proof 9: Is the objective we want to minimize when performing mle [def. 5.3] for a logistic regression likelihood and incurs higher cost for samples closer to the decision boundary:

l\_l(w; x, y) := log(1 + exp(-y \* w^T x)) (5.20)
alpha log(1 + e^z) = { z for large z, 0 for small z }

Corollary 5.6 MLE for Logistic Regression:

ln(w) = sum\_{i=1}^n l\_l = sum\_{i=1}^n log(1 + exp(-yi \* w^T xi)) (5.21)

Stochastic Gradient Descent

The logistic loss l\_l is a convex function. Thus we can use convex optimization techniques s.a. SGD in order to minimize the objective corollary 5.6.

Definition 5.15 Logistic Loss Gradient proof 9: nabla\_w l\_l(w) = P(Y = -y|x, w) \* (-y \* x)

= 1/(1 + exp(y \* w^T x)) \* (-y \* x) (5.22)

Explanation 5.2.

nabla\_w l\_l(w) = P(Y = -y|x, w) \* (-y \* x) alpha nabla\_w l\_H(w)
The logistic loss l\_l is equal to the hinge loss l\_h but weighted by the probability of being in the wrong class P(Y = -1|x, w). Thus the more likely we are in the wrong class the bigger the step we take:

P(Y = -y|y = w^T x) = { up arrow take big step, down arrow take small step }

Algorithm 5.1 Vanilla SGD for Logistic Regression:

Initialize: w
1: for 1, 2, ..., T do
2: Pick (x, y) unif. at random from data D
3: P(Y = -y|x, w) = 1/(1 + exp(-y \* w^T x)) = sigma(y \* w^T x)
 compute prob. of misclassif. with cur. model
4: w = w + eta \* y \* x \* sigma(y \* w^T x)
5: end for

Making Predictions

Given an optimal parameter vector w-hat found by algorithm 5.1 we can predict the output of a new label by eq. (5.19):

P(y|x, w-hat) = 1/(1 + exp(-y \* w-hat^T x)) (5.23)

Drawback

Logistic regression, does not tell us anything about the likelihood P(Y = 1|x') of a point, thus it will not be able to detect outliers, as it will assign a very high probability to all correctly classified points, far from the decision boundary.

8.2.2. Maximum a-Posteriori Estimates

8.3. Logistic regression and regularization

Adding Priors to Logistic Likelihood

L2 (Gaussian prior):

arg min\_w sum\_{i=1}^n log(1 + exp(-yi \* w^T xi)) + lambda ||w||\_2^2

L1 (Laplace prior):

arg min\_w sum\_{i=1}^n log(1 + exp(-yi \* w^T xi)) + lambda ||w||\_1

Generalized:

w-hat = arg min\_w sum\_{i=1}^n log(1 + exp(-yi \* w^T xi)) + lambda C(w)
= arg max\_w P(w|X, Y)

8.4. SGD for L2-gregularized logistic regression

**Initialize:**  $\boldsymbol{w}$

1: **for**  $1, 2, \dots, T$  **do**

2:   Pick  $(\boldsymbol{x}, y)$  unif. at randomn from data  $\mathcal{D}$

3:    $\hat{\mathbb{P}}(Y = -y|\boldsymbol{x}, \boldsymbol{w}) = \frac{1}{(1+\exp(-y \cdot \boldsymbol{w}^\top \boldsymbol{x}))}$   
       ▷ compute prob. of misclassif. with cur. model

4:    $\boldsymbol{w} = \boldsymbol{w}(1 - 2\lambda\eta_t) + \eta_t y \boldsymbol{x}$   $\hat{\mathbb{P}}(Y = -y|\boldsymbol{x}, \boldsymbol{w})$

5: **end for**

**Thus:**  $\boldsymbol{w}$  is pulled/shrunken towards zero, depending on the regularization parameter  $\lambda > 0$

## 9. Proofs

Proof.

[def. 5.13]

We need to only proof the second expression, as the first one is fulfilled anyway:

$$1 - \frac{1}{1 + e^z} = \frac{1 + e^z}{1 + e^z} - \frac{1}{1 + e^z} = \frac{e^z + 1 - 1}{1 + e^z} = \frac{e^z}{e^z + 1}$$

$$= \frac{1}{1 + e^{-z}}$$

□

Proof.

[def. 5.14]

$$l_n(\boldsymbol{w}) = \arg \max_{\boldsymbol{w}} \mathbb{P}(y_{1:n}|\boldsymbol{x}_{1:n}, \boldsymbol{w}) = \arg \min_{\boldsymbol{w}} -\log \mathbb{P}(Y|\boldsymbol{X}, \boldsymbol{w})$$

$$\stackrel{\text{i.i.d.}}{=} \arg \min_{\boldsymbol{w}} \sum_{i=1}^n -\log \mathbb{P}(y_i|\boldsymbol{x}_i, \boldsymbol{w})$$

$$\stackrel{\text{eq. (5.19)}}{=} -\log \frac{1}{1 + \exp(-y_i \cdot \boldsymbol{w}^\top \boldsymbol{x}_i)}$$

$$= \log(1 + \exp(-y_i \cdot \boldsymbol{w}^\top \boldsymbol{x}_i)) =: l_l(\boldsymbol{w})$$

□

Proof.

[def. 5.15]

$$\nabla_{\boldsymbol{w}} l_l(\boldsymbol{w}) = \frac{\partial}{\partial \boldsymbol{w}} \log(1 + \exp(-y \cdot \boldsymbol{w}^\top \boldsymbol{x}))$$

$$\stackrel{\text{C.R.}}{=} \frac{1}{(1 + \exp(-y \cdot \boldsymbol{w}^\top \boldsymbol{x}))} \frac{\partial}{\partial \boldsymbol{w}} (1 + \exp(-y \cdot \boldsymbol{w}^\top \boldsymbol{x}))$$

$$\stackrel{\text{C.R.}}{=} \frac{1}{(1 + \exp(-y \cdot \boldsymbol{w}^\top \boldsymbol{x}))} \exp(-y \cdot \boldsymbol{w}^\top \boldsymbol{x}) \cdot (-y\boldsymbol{x})$$

$$= \frac{e^{-z} \cdot (-yx)}{(1 + e^{-z})} = \frac{-yx}{e^z(1 + e^{-z})} = \frac{-yx}{(e^z + e^{-z} + z)}$$

$$= \frac{1}{\exp(y \cdot \boldsymbol{w}^\top \boldsymbol{x}) + 1} \cdot (-yx)$$

$$\stackrel{\text{eq. (5.19)}}{=} \hat{\mathbb{P}}(Y = -y|\boldsymbol{x}, \boldsymbol{w}) \cdot (-y\boldsymbol{x})$$

□

## Bayesian Inference/Modeling

**Definition 5.16 Bayesian Inference:** So far we only really looked at point estimators/estimates<sup>[def. 23.47]</sup>. But what if we are interested not only into the most likely value but also want to have a notion of the uncertainty of our prediction? Bayesian inference refers to statistical inference<sup>[def. 4.13]</sup>, where uncertainty in inferences is quantified using probability. Thus we usually obtain a distribution over our parameters and not a single point estimates  $\Rightarrow$  can deduce statistical properties of parameters from their distributions.

**Definition 5.17**  $p(w|y, X)/p(w|D)$   
**Posterior Probability Distribution:**  
 ① Specify the prior  $p_\lambda(w)$   
 ② Specify the likelihood  $p(y|w, X)/p(D|w)$   
 ③ Calculate the evidence  $p(y|X)/p(D)$   
 ④ Calculate the posterior distribution  $p(w|y, X)/p(w|D)$   

$$p(w|y, X) = \frac{p(y|w, X) \cdot p_\lambda(w)}{p(y|X)} = \frac{\text{Likelihood} \cdot \text{Prior}}{\text{Normalization}}$$

**Definition 5.18**  $p(y|X)/p(D)$   
**Marginal Likelihood** [see proof 4]: is the normalization constant that makes sure that the posterior distribution<sup>[def. 5.17]</sup> is an true probability distribution:  

$$p(y|X) = \int p(y|w, X) \cdot p_\lambda(w) dw = \int \text{Likelihood} \cdot \text{Prior} dw \quad (5.24)$$

**Note**  
 It is called marginal likelihood as we marginalize over all possible parameter values.

**Definition 5.19**  $p(f_*|x_*, X, y)/p(f_*|y)$   
**Posterior Predictive Distribution:** is the distribution of a real process  $f$  (i.e.  $f(x) = x^\top w$ ) given:  
 • new observation(s)  $x_*$   
 • the posterior distribution<sup>[def. 5.17]</sup> of the observed data  $D = \{X, y\}$   
 • The likelihood of a real process  $f_*$   

$$p(f_*|x_*, X, y) = \int p(f_*|x_*, w) \cdot p(w|X, y) dw \quad (5.25)$$

it is calculated by weighting the likelihood<sup>[def. 5.1]</sup> of the new observation  $x_*$  with the posterior of the observed data and averaging over all parameter values  $w$  see section 4.  
 $\Rightarrow$  obtain a distribution not depending on  $w$ .

**Note  $f$  vs.  $y$**   
 • Usually  $f$  denotes the model i.e.:  
 $f(x) = x^\top w$  or  $f(x) = \phi(x)^\top w$   
 and  $y$  the model plus the noise  $y = f(x) + \epsilon$ .  
 • Sometime people also write only:  $p(y_*|x_*, X, y)$

### 10. Types of Uncertainty

**Definition 5.20 Epistemic/Systematic Uncertainty:**  
 Is the uncertainty that is due to things that one could in principle know but does not i.e. only having a finite sub sample of the data. The epistemic noise will decrease the more data we have.

**Definition 5.21 Aleatoric/Statistical Uncertainty:**  
 Is the uncertainty of an underlying random process/model. The aleatoric uncertainty stems from the fact that we create random process models. If we run our *trained* model multiple times with the *same* input  $X$  data we will end up with different outcomes  $\hat{y}$ . The aleatoric noise is *irreducible* as it is an underlying part of probabilistic models.

## Bayesian Filtering

Figure 4: This problem corresponds to a *hidden Markov model (HMM)??*  

$$x_t = (x_{t,1} \quad \dots \quad x_{t,n}) \quad y_t = (y_{t,1} \quad \dots \quad y_{t,m})$$

**Note**  
 Comes from the idea that spam can be filtered out by the probability of certain words.

**Definition 6.2**  $x_{t+1} \sim p(x_t|x_{t-1})$   
**Process/Motion/Dynamic Model:** is a model  $q$  of how our system state  $x_t$  evolves and is usually fraught with some uncertainty.

**Corollary 6.1 Markov Property**  $x_t \perp x_{1:t-2}|x_{t-1}$ : The process models<sup>[def. 6.2]</sup> is Markovian<sup>[def. 24.10]</sup> i.e. the current state depends only on the previous state:  

$$p(x_t|x_{1:t-1}) = p(x_t|x_{t-1}) \quad (6.1)$$

**Definition 6.3**  $y_t \sim p(y_t|x_t)$   
**Measurement/Sensor-Model/Likelihood:** is a model  $q$  that maps observations/sensor measurements of our model  $y_t$  to the model state  $x_t$

**Corollary 6.2**  $y_t \perp y_{1:t-1}x_{1:t-1}|x_t$   
**Conditional Independent Measurements:** The measurements  $y_t$  are conditionally independent of the previous observations  $y_{1:t-1}$  given the current state  $x_t$ :  

$$p(y_t|y_{1:t-1}, x_t) = p(y_t|x_t) \quad (6.2)$$

**Goal**  
 We want to combine the process model<sup>[def. 6.2]</sup> and the measurement model<sup>[def. 6.3]</sup> in a recursive way to obtain a good estimate of our model state:  

$$\left. \begin{array}{l} p(x_t|x_{t-1}) \\ p(y_t|x_t) \end{array} \right\} p(x_t|y_{1:t}) \xrightarrow[\text{recursion rule}]{p(x_{t+1}|y_{1:t})} p(x_{t+1}|y_{1:t+1})$$

**Definition 6.4 Chapman-Kolmogorov eq.**  $p(x_t|y_{1:t-1})$   
**Prior Update/Prediction Step** [see section 4]:  

$$p(x_t|y_{1:t-1}) = \int p(x_t|x_{t-1})p(x_{t-1}|y_{1:t-1}) dx_{t-1} \quad (6.3)$$
**Prior Distribution:**  

$$p(x_0|y_{0-1}) = p(x_0) = p_0 \quad (6.4)$$

**Definition 6.5**  $p(x_t|y_{1:t})$   
**Posterior Distribution/Update Step** [see section 4]:  

$$p(x_t|y_{1:t}) = \frac{1}{Z_t} p(y_t|x_t) p(x_t|y_{1:t-1}) \quad (6.5)$$

**Definition 6.6 Normalization** [see proof 4]:  

$$Z_t = p(y_t|y_{1:t-1}) = \int p(y_t|x_t)p(x_t|y_{1:t-1}) dx_t \quad (6.6)$$

**Algorithm 6.1 Optimal Bayesian Filtering:**  
 1: **Input:**  $p(x_0)$   
 2: **while** Stopping Criterion not full-filled **do**  
 3:   **Prediction Step:**  

$$p(x_t|y_{1:t}) = \frac{1}{Z_t} p(y_t|x_t)p(x_t|y_{1:t-1})$$
  
 4:   **Update Step:**  

$$p(x_t|y_{1:t-1}) = \int p(x_t|x_{t-1})p(x_{t-1}|y_{1:t-1}) dx_{t-1}$$
  
     **with:**  

$$Z_t = \int p(y_t|x_t)p(x_t|y_{1:t-1}) dx_t$$
  
 5: **end while**

**Corollary 6.3** [see proof 4]  
**Joint Probability Distribution of (HMM):** we can also calculate the joint probability distribution of the (HMM):  

$$p(x_{1:t}, y_{1:t}) = p(x_1)p(y_1|x_1) \prod_{i=2}^t p(x_i|x_{i-1})p(y_i|x_i) \quad (6.7)$$

**Example 6.1 Types of Bayesian Filtering:**  
 • **Kalman Filter:** assumes a *linear* system,  $q, h$  are linear and Gaussian noise  $v, w$ .  
 • **Extended Kalman Filter:** assumes a *non-linear* system,  $q, h$  are non-linear and Gaussian noise  $v, w$ .  
 • **Particle Filter:** assumes a *non-linear* system  $q, h$  are non-linear and Non-Gaussian noise  $v, w$ , especially multi-modal distributions.

### 1. Kalman Filters

**Definition 6.7 Kalman Filter Assumptions:** Assumes a *linear*<sup>[def. 13.13]</sup> process model<sup>[def. 6.2]</sup>,  $q$  with Gaussian model-noise  $v$  and a linear measurement model<sup>[def. 6.3]</sup>  $h$  with Gaussian process-noise  $w$ .

**Definition 6.8 Kalman Filter Model:**  
**Process Model** (6.8)

$$x^{(k)} = A^{(k-1)}x^{(k-1)} + u^{(k-1)} + v[k-1] \quad \text{with} \quad x^{(0)} \sim \mathcal{N}(x_0, P_0) \quad \text{and} \quad v^{(k)} \sim \mathcal{N}(0, Q^{(k)}) \quad (6.9)$$

**Measurement Model**  

$$z^{(k)} = H^{(k)}x^{(k)} + w^{(k-1)} \quad \text{with} \quad w^{(k)} \sim \mathcal{N}(0, R^{(k)})$$

**and define:**  

$$\hat{x}_p^{(k)} := \mathbb{E}[x_p^{(k)}] \quad \text{and} \quad P_p^{(k)} := \mathbb{V}\left[x_p^{(k)}\right] \quad (6.10)$$

$$\hat{x}_m^{(k)} := \mathbb{E}[x_m^{(k)}] \quad \text{and} \quad P_m^{(k)} := \mathbb{V}\left[x_m^{(k)}\right] \quad (6.11)$$

**Note**  
 The CRVs  $x_0, \{v(\cdot)\}, \{w(\cdot)\}$  are mutually independent.  
 old Kalman algorithm (in slides Joseph Form 1 think)

## Gaussian Processes (GP)

### 1. Gaussian Process Regression

#### 1.1. Gaussian Linear Regression

**Given**  
 ① Linear Model with Gaussian Noise:  

$$f(x) = w^\top x \quad \epsilon \sim \mathcal{N}(0, \sigma_n^2 I) \quad (7.1)$$

$$y = f(x) + \epsilon$$
 $\Rightarrow$  Gaussian Likelihood:  $p(y|X, w) = \mathcal{N}(Xw, \sigma_n^2 I)$   
 ② Gaussian Prior:  $p(w) = \mathcal{N}(0, \Sigma_p)$

**Sought**  
 ① Posterior Distribution:  $p(w|y, X)$   
 ② Posterior Predictive Distribution:  $p(f_*|x_*, X, y)$

**Definition 7.1**  $p(w|y, X) = \mathcal{N}(\bar{w}, \Sigma_w^{-1})$   
**Posterior Distribution** proof 4:  

$$\mu_w = \frac{1}{\sigma_n^2} \Sigma_w^{-1} X y \quad \Sigma_w = \frac{1}{\sigma_n^2} X X^\top + \Sigma_p^{-1}$$

**Note**  
 We could also use a prior with non-zero mean  $p(w) = \mathcal{N}(\mu, \Sigma_p)$  but by convention w.o.l.g. we use zero mean see ??.

**Definition 7.2**  $p(f_*|x_*, X, y) = \mathcal{N}(\mu_*, \Sigma_*)$   
**Posterior Predictive Distribution** proof 4:  

$$\mu_* = \frac{1}{\sigma_n^2} x_*^\top \Sigma_w^{-1} X y \quad \Sigma_* = x_*^\top \Sigma_w^{-1} x_* \quad (7.2)$$

#### 1.2. Kernelized Gaussian Linear Regression

**Definition 7.3 Posterior Predictive Distribution:**  

$$p(f_*|x_*, X, y) = \mathcal{N}(\mu_*, \Sigma_*) \quad (7.3)$$

$$\mu_* \quad (7.4)$$

### 2. Model Selection

#### 2.1. Marginal Likelihood

# Approximate Inference

<p><b>Problem</b></p> <p>In statistical inference we often want to calculate integrals of probability distributions i.e.</p> <ul style="list-style-type: none"> <li>Expectations</li> </ul> $\mathbb{E}_{X \sim \mathbf{p}}[g(X)] = \int g(x) \mathbf{p}(x) dx$ <ul style="list-style-type: none"> <li>Normalization constants:</li> </ul> $\mathbf{p}(\theta y) = \frac{1}{Z} \mathbf{p}(\theta, y) \quad Z = \int \mathbf{p}(y \theta) \mathbf{p}(\theta) d\theta$ $= \int \mathbf{p}(\theta) \prod_{i=1}^n \mathbf{p}(y_i   x_i, \theta) d\theta$ <p>For non-linear distributions this integrals are in general intractable which may be due to the fact that there exist no analytic form of the distribution we want to integrate or highly dimensional latent spaces that prohibits numerical integration (curse of dimensionality).</p>	<p><b>Definition 8.1 Approximate Inference:</b> Is the procedure of finding an probability distribution <math>q</math> that approximates a true probability distribution <math>\mathbf{p}</math> as well as possible.</p>
<p><b>1. Variational Inference</b></p>	<p><b>Definition 8.2 Bayes Variational Inference:</b> Given an unnormalized (posterior) probability distribution:</p> $\mathbf{p}(\theta y) = \frac{1}{Z} \mathbf{p}(\theta, y) \quad (8.1)$ <p>seeks an <i>approximate</i> probability distribution <math>q_\lambda</math>, that is parameterized by a <i>variational parameter</i> <math>\lambda</math> and approximates <math>\mathbf{p}(\theta y)</math> well.</p>
<p><b>Definition 8.3 Variational Family of Distributions <math>Q</math>:</b> a set of probability distributions <math>Q</math> that is parameterized by the same <i>variational parameter</i> <math>\lambda</math> is called a variational family.</p>	<p><b>Definition 8.1</b> <b>Approximate Inference:</b> Is the procedure of finding an probability distribution <math>q</math> that approximates a true probability distribution <math>\mathbf{p}</math> as well as possible.</p>
<p><b>1.1. Laplace Approximation</b></p>	<p><b>Definition 8.2</b> <b>Bayes Variational Inference:</b> Given an unnormalized (posterior) probability distribution:</p> $\mathbf{p}(\theta y) = \frac{1}{Z} \mathbf{p}(\theta, y) \quad (8.1)$ <p>seeks an <i>approximate</i> probability distribution <math>q_\lambda</math>, that is parameterized by a <i>variational parameter</i> <math>\lambda</math> and approximates <math>\mathbf{p}(\theta y)</math> well.</p>
<p><b>Definition 8.4</b> <b>Laplace Approximation:</b> Tries to approximate a desired probability distribution <math>\mathbf{p}(\theta \mathcal{D})</math> by a Gaussian probability distribution:</p> $Q = \{q_\lambda(\theta) = \mathcal{N}(\lambda)\} = \mathcal{N}(\mu, \Sigma) \quad (8.2)$ <p>the distribution is given by:</p> $q(\theta) = c \cdot \mathcal{N}(\theta; \lambda_1, \lambda_2) \quad (8.3)$ <p>with</p> $\lambda_1 = \hat{\theta} = \arg \max_{\theta} \mathbf{p}(\theta y)$ $\lambda_2 = \Sigma = H^{-1}(\hat{\theta}) = -\nabla \nabla_{\theta} \log \mathbf{p}(\hat{\theta} y)$	<p><b>Definition 8.3</b> <b>Bayes Variational Inference:</b> Given an unnormalized (posterior) probability distribution:</p> $\mathbf{p}(\theta y) = \frac{1}{Z} \mathbf{p}(\theta, y) \quad (8.1)$ <p>seeks an <i>approximate</i> probability distribution <math>q_\lambda</math>, that is parameterized by a <i>variational parameter</i> <math>\lambda</math> and approximates <math>\mathbf{p}(\theta y)</math> well.</p>
<p><b>Corollary 8.1 :</b> Taylor approximation of a function <math>\mathbf{p}(\theta y) \in \mathcal{C}^k</math> around its mode <math>\hat{\theta}</math> naturally induces a Gaussian approximation. See proofs 4,4,4</p>	<p><b>Definition 8.3</b> <b>Bayes Variational Inference:</b> Given an unnormalized (posterior) probability distribution:</p> $\mathbf{p}(\theta y) = \frac{1}{Z} \mathbf{p}(\theta, y) \quad (8.1)$ <p>seeks an <i>approximate</i> probability distribution <math>q_\lambda</math>, that is parameterized by a <i>variational parameter</i> <math>\lambda</math> and approximates <math>\mathbf{p}(\theta y)</math> well.</p>
<p><b>1.2. Black Box Stochastic Variational Inference</b></p>	<p><b>Definition 8.2</b> <b>Bayes Variational Inference:</b> Given an unnormalized (posterior) probability distribution:</p> $\mathbf{p}(\theta y) = \frac{1}{Z} \mathbf{p}(\theta, y) \quad (8.1)$ <p>seeks an <i>approximate</i> probability distribution <math>q_\lambda</math>, that is parameterized by a <i>variational parameter</i> <math>\lambda</math> and approximates <math>\mathbf{p}(\theta y)</math> well.</p>
<p>The most common way of finding <math>q_\lambda</math> is by minimizing the KL-divergence<sup>[def. 4.6]</sup> between our approximate distribution <math>q</math> and our true posterior <math>\mathbf{p}</math>:</p> $q^* \in \arg \min_{q \in Q} \text{KL}(q(\theta) \parallel \mathbf{p}(\theta y)) = \arg \min_{\lambda \in \mathbb{R}^d} \text{KL}(q_\lambda(\theta) \parallel \mathbf{p}(\theta y))$	<p><b>Definition 8.3</b> <b>Bayes Variational Inference:</b> Given an unnormalized (posterior) probability distribution:</p> $\mathbf{p}(\theta y) = \frac{1}{Z} \mathbf{p}(\theta, y) \quad (8.1)$ <p>seeks an <i>approximate</i> probability distribution <math>q_\lambda</math>, that is parameterized by a <i>variational parameter</i> <math>\lambda</math> and approximates <math>\mathbf{p}(\theta y)</math> well.</p>
<p><b>Note</b></p> <p>Usually we want to minimize <math>\text{KL}(\mathbf{p}(\theta y) \parallel q(\theta))</math> but this is often infeasible s.t. we only minimize <math>\text{KL}(q(\theta) \parallel \mathbf{p}(\theta y))</math></p>	<p><b>Definition 8.3</b> <b>Bayes Variational Inference:</b> Given an unnormalized (posterior) probability distribution:</p> $\mathbf{p}(\theta y) = \frac{1}{Z} \mathbf{p}(\theta, y) \quad (8.1)$ <p>seeks an <i>approximate</i> probability distribution <math>q_\lambda</math>, that is parameterized by a <i>variational parameter</i> <math>\lambda</math> and approximates <math>\mathbf{p}(\theta y)</math> well.</p>
<p><b>Definition 8.5 ELBO-Optimization Problem</b> proof 4:</p> $q_\lambda^* \in \arg \min_{\lambda: q_\lambda \in Q} \text{KL}(q_\lambda(\theta) \parallel \mathbf{p}(\theta y))$ $= \arg \max_{\lambda: q_\lambda \in Q} \mathbb{E}_{\theta \sim q_\lambda} [\log \mathbf{p}(y, \theta)] + H(q_\lambda) \quad (8.4)$ $= \arg \max_{\lambda: q_\lambda \in Q} \mathbb{E}_{\theta \sim q_\lambda} [\log \mathbf{p}(y \theta)] - \text{KL}(q_\lambda(\theta) \parallel \mathbf{p}(\theta)) \quad (8.5)$ $:= \arg \max_{\lambda: q_\lambda \in Q} \text{ELBO}(\lambda) \quad (8.6)$	<p><b>Definition 8.3</b> <b>Bayes Variational Inference:</b> Given an unnormalized (posterior) probability distribution:</p> $\mathbf{p}(\theta y) = \frac{1}{Z} \mathbf{p}(\theta, y) \quad (8.1)$ <p>seeks an <i>approximate</i> probability distribution <math>q_\lambda</math>, that is parameterized by a <i>variational parameter</i> <math>\lambda</math> and approximates <math>\mathbf{p}(\theta y)</math> well.</p>

**Attention:** Sometimes people write simply  $\mathbf{p}$  for the posterior and  $\mathbf{p}(\cdot)$  for prior.

**Explanation 8.1.**

- eq. (8.4):
  - prefer uncertain approximations i.e. we maximize  $H(q)$
  - that jointly make the joint posterior likely
- eq. (8.6): Expected likelihood of our posterior over  $q$  minus a regularization term that makes sure that we are not too far away from the prior.

**1.3. Expected Lower Bound of Evidence (ELBO)**

**Definition 8.6** example 8.2/proof 4  
**Expected Lower Bound of Evidence (ELBO):**  
The evidence lower bound is a bound on the log prior:

$$\text{ELBO}(q_\lambda) \leq \log \mathbf{p}(y) \quad (8.7)$$

**1.3.1. Maximizing The ELBO**

**Definition 8.7 Gradient of the ELBO Loss:**

$$\nabla_\lambda L(\lambda) = \nabla_\lambda \text{ELBO}(\lambda) \quad (8.8)$$

$$= \nabla_\lambda \left[ \mathbb{E}_{\theta \sim q_\lambda} [\log \mathbf{p}(y, \theta)] + H(q_\lambda) \right]$$

$$= \nabla_\lambda \left[ \mathbb{E}_{\theta \sim q_\lambda} [\log \mathbf{p}(y|\theta)] - \text{KL}(q_\lambda(\theta) \parallel \mathbf{p}(\theta)) \right]$$

$$= \nabla_\lambda \mathbb{E}_{\theta \sim q_\lambda} [\log \mathbf{p}(y|\theta)] - \nabla_\lambda \text{KL}(q_\lambda(\theta) \parallel \mathbf{p}(\theta))$$

**Problem**

In order to use SGD we need to evaluate the gradient of the loss:

$$\nabla_\lambda \mathbb{E} [l(\theta; \mathbf{x})] = \mathbb{E} [\nabla_{\mathbf{x} \sim \mathbf{p}} l(\theta; \mathbf{x})] = \frac{1}{m} \sum_{i=1}^m \nabla_{\mathbf{x} \sim \mathbf{p}} l(\theta; \mathbf{x})$$

however in eq. (8.8) only second term can be derived easily. For the first term we cannot move the gradient inside the expectation as the expectations depends on the parameter w.r.t. which we differentiate:

$$\nabla_\lambda \mathbb{E}_{\theta \sim q_\lambda} [\log \mathbf{p}(y|\theta)] = \frac{\partial}{\partial \lambda} \int q_\lambda \log \mathbf{p}(y|\theta) d\theta$$

**Solutions:**

- Score Gradients
- Reparameterization Trick: reparameterize a function s.t. it depends on another parameter and reformulate it s.t. it still returns the same value.

**1.4. The Reparameterization Trick**

**Principle 8.1** proof 4  
**Reparameterization Trick:** Let  $\phi$  some base distribution from which we can sample and assume there exist an invertible function  $g$  s.t.  $\theta = g(\epsilon, \lambda)$  then we can write  $\theta$  in terms of a new distribution parameterized by  $\epsilon \sim \phi(\epsilon)$ :

$$\theta \sim q(\theta|\lambda) = \phi(\epsilon) |\nabla_\epsilon g(\epsilon; \lambda)|^{-1} \quad (8.9)$$

we can then write by the law of the unconscious statistician law 21.6:

$$\mathbb{E}_{\theta \sim q_\lambda} [\log \mathbf{p}(y|\theta)] = \mathbb{E}_{\epsilon \sim \phi} [\log \mathbf{p}(y|g(\epsilon; \lambda))] \quad (8.10)$$

$\Rightarrow$  the expectations does not longer depend on  $\lambda$  and we can pull in the gradient!

$$\nabla_\lambda \mathbb{E}_{\theta \sim q_\lambda} [\log \mathbf{p}(y|\theta)] = \nabla_\epsilon \mathbb{E}_{\theta \sim \phi} [\log \mathbf{p}(y|g(\epsilon; \lambda))] \quad (8.11)$$

$$= \mathbb{E}_{\epsilon \sim \phi} [\nabla_\lambda \log \mathbf{p}(y|g(\epsilon; \lambda))] \quad (8.12)$$

**Definition 8.8** example 8.3  
**Reparameterized ELBO Gradient**<sup>[def. 8.7]</sup>:  
By using the reparameterization trick principle 8.2 we can write the gradient of the ELBO as:

$$\nabla_\lambda L(\lambda) = \nabla_\lambda \text{ELBO}(\lambda) \quad (8.13)$$

$$= \nabla_\lambda \mathbb{E}_{\theta \sim q_\lambda} [\log \mathbf{p}(y|\theta)] - \nabla_\lambda \text{KL}(q_\lambda(\theta) \parallel \mathbf{p}(\theta))$$

$$= \mathbb{E}_{\epsilon \sim \phi} [\nabla_\lambda \log \mathbf{p}(y|g(\epsilon; \lambda))] - \nabla_\lambda \text{KL}(q_\lambda(\theta) \parallel \mathbf{p}(\theta))$$

**Corollary 8.2** proof 8.3  
**Reparameterized ELBO for Gaussians:**

$$\nabla_\lambda L(\lambda) = \nabla_\lambda \text{ELBO}(\lambda) \quad (8.14)$$

$$= \nabla_\lambda \mathbb{E}_{\theta \sim q_\lambda} [\log \mathbf{p}(y|\theta)] - \nabla_\lambda \text{KL}(q_\lambda(\theta) \parallel \mathbf{p}(\theta))$$

$$= \mathbb{E}_{\epsilon \sim \mathcal{N}(0, I)} [\nabla_{C, \mu} \log \mathbf{p}(y|C\epsilon + \mu)] - \nabla_{C, \mu} \text{KL}(q_{C, \mu} \parallel \mathbf{p}(\theta))$$

$$\approx \frac{n}{m} \sum_{j=1}^m \nabla_{C, \mu} \log \mathbf{p}(y_{ij} | C\epsilon^j + \mu, x_{ij}) - \nabla_{C, \mu} \text{KL}(q_{C, \mu} \parallel \mathbf{p}(\theta))$$

**2. Markov Chain Monte Carlos Methods**

**Principle 8.2** proof 4  
**Reparameterization Trick:** Let  $\phi$  some base distribution from which we can sample and assume there exist an invertible function  $g$  s.t.  $\theta = g(\epsilon, \lambda)$  then we can write  $\theta$  in terms of a new distribution parameterized by  $\epsilon \sim \phi(\epsilon)$ :

$$\theta \sim q(\theta|\lambda) = \phi(\epsilon) |\nabla_\epsilon g(\epsilon; \lambda)|^{-1} \quad (8.15)$$

we can then write by the law of the unconscious statistician law 21.6:

$$\mathbb{E}_{\theta \sim q_\lambda} [\log \mathbf{p}(y|\theta)] = \mathbb{E}_{\epsilon \sim \phi} [\log \mathbf{p}(y|g(\epsilon; \lambda))] \quad (8.16)$$

$\Rightarrow$  the expectations does not longer depend on  $\lambda$  and we can pull in the gradient!

$$\nabla_\lambda \mathbb{E}_{\theta \sim q_\lambda} [\log \mathbf{p}(y|\theta)] = \nabla_\epsilon \mathbb{E}_{\theta \sim \phi} [\log \mathbf{p}(y|g(\epsilon; \lambda))] \quad (8.17)$$

$$= \mathbb{E}_{\epsilon \sim \phi} [\nabla_\lambda \log \mathbf{p}(y|g(\epsilon; \lambda))] \quad (8.18)$$

**Definition 8.9** example 8.3  
**Reparameterized ELBO Gradient**<sup>[def. 8.7]</sup>:  
By using the reparameterization trick principle 8.2 we can write the gradient of the ELBO as:

$$\nabla_\lambda L(\lambda) = \nabla_\lambda \text{ELBO}(\lambda) \quad (8.19)$$

$$= \nabla_\lambda \mathbb{E}_{\theta \sim q_\lambda} [\log \mathbf{p}(y|\theta)] - \nabla_\lambda \text{KL}(q_\lambda(\theta) \parallel \mathbf{p}(\theta))$$

$$= \mathbb{E}_{\epsilon \sim \phi} [\nabla_\lambda \log \mathbf{p}(y|g(\epsilon; \lambda))] - \nabla_\lambda \text{KL}(q_\lambda(\theta) \parallel \mathbf{p}(\theta))$$

**Corollary 8.3** proof 8.3  
**Reparameterized ELBO for Gaussians:**

$$\nabla_\lambda L(\lambda) = \nabla_\lambda \text{ELBO}(\lambda) \quad (8.20)$$

$$= \nabla_\lambda \mathbb{E}_{\theta \sim q_\lambda} [\log \mathbf{p}(y|\theta)] - \nabla_\lambda \text{KL}(q_\lambda(\theta) \parallel \mathbf{p}(\theta))$$

$$= \mathbb{E}_{\epsilon \sim \mathcal{N}(0, I)} [\nabla_{C, \mu} \log \mathbf{p}(y|C\epsilon + \mu)] - \nabla_{C, \mu} \text{KL}(q_{C, \mu} \parallel \mathbf{p}(\theta))$$

$$\approx \frac{n}{m} \sum_{j=1}^m \nabla_{C, \mu} \log \mathbf{p}(y_{ij} | C\epsilon^j + \mu, x_{ij}) - \nabla_{C, \mu} \text{KL}(q_{C, \mu} \parallel \mathbf{p}(\theta))$$

## 3. Bayesian Neural Networks (BNN)

**Definition 8.10 Bayesian Neural Networks (BNN):**

① Model the prior over our weights  $\theta = [W^0 \dots W^L]$  by a neural network:

$$\theta \sim \mathbf{p}_\lambda(\theta) = \mathbf{F} \quad \text{with} \quad \mathbf{F} = \mathbf{F}^L \circ \dots \circ \mathbf{F}^1$$

$$\mathbf{F}^l = \varphi \circ \bar{\mathbf{F}}^l = \varphi(W^l \mathbf{x} + \mathbf{b}^l)$$

for each weight  $w_{k,j}^{(0)}$  of input  $x_j$  with weight on the hidden variable  $z_k^{(0)}$  with  $a_i^0 = \varphi\{z_i^{(0)}\}$  it follows:

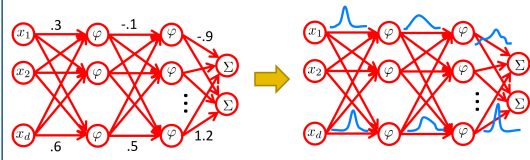

$$w_{k,j}^{(0)} = \mathbf{p}_w(\lambda_{k,j}) \stackrel{\text{i.e.}}{=} \mathcal{N}(\mu_{k,j}, \sigma_{k,j}^2)$$

Figure 5

② The parameters of likelihood function are modeled by the output of the network:

$$\mathbf{p}(y|F(\theta, \mathbf{X})) \quad \text{see example 8.4} \quad (8.21)$$

<p><b>Note</b></p> <p>Recall for normal Bayesian Linear regression we had:</p>	<p><b>Problem</b></p> <p>All the weights of the prior <math>\mathbf{p}_\lambda(\theta) = \mathbf{F}</math> are correlated in some complex way see Figure 5. Thus even if the prior and likelihood are simple, the posterior will be not. <math>\Rightarrow</math> need to approximate the posterior <math>\mathbf{p}(\theta \mathbf{y}, \mathbf{X})</math> i.e. by fitting a Gaussian distribution to each weight of the posterior neural network.</p>
<p><b>3.0.1. MAP estimates for BNN</b></p>	<p><b>Definition 8.11 BNN MAP Estimate:</b> We need to do a forward pass for each <math>\mathbf{x}_i</math> in order to obtain <math>\mu(\mathbf{x}_i; \theta)</math> and <math>\sigma(\mathbf{x}_i; \theta)^2</math>:</p> $\theta^* = \arg \max_{\theta} \{\mathbf{p}(\theta \mathbf{X}, \mathbf{y})\} \stackrel{\text{eq. (5.13)}}{=} \arg \min_{\theta} \lambda \ \theta\ _2^2$ $= \arg \min_{\theta} \left( \sum_{i=1}^n \left( \frac{1}{2\sigma(\mathbf{x}_i; \theta)^2} \ y_i - \mu(\mathbf{x}_i; \theta)\ ^2 + \frac{1}{2} \log \sigma(\mathbf{x}_i; \theta)^2 \right) \right)$

## 4. Proofs

*Proof.* Definition 5.19:

$$\begin{aligned} \mathbf{p}(\mathbf{f}_*|\mathbf{x}_*, \mathbf{X}, \mathbf{y}) &= \frac{\mathbf{p}(\mathbf{f}_*, \mathbf{x}_*, \mathbf{X}, \mathbf{y})}{\mathbf{p}(\mathbf{x}_*, \mathbf{X}, \mathbf{y})} \\ &= \frac{\int \mathbf{p}(\mathbf{f}_*, \mathbf{x}_*, \mathbf{X}, \mathbf{y}, w) \mathbf{p}(\mathbf{x}_*, \mathbf{X}, w) dw}{\mathbf{p}(\mathbf{x}_*, \mathbf{X}, \mathbf{y})} \\ \text{eq. (21.19)} \quad &\frac{\int \mathbf{p}(\mathbf{f}_*|\mathbf{x}_*, \mathbf{X}, \mathbf{y}, w) \mathbf{p}(\mathbf{x}_*, \mathbf{X}, w) dw}{\mathbf{p}(\mathbf{x}_*, \mathbf{X}, \mathbf{y})} \\ \text{eq. (21.19)} \quad &\frac{\int \mathbf{p}(\mathbf{f}_*|\mathbf{x}_*, \mathbf{X}, \mathbf{y}, w) \mathbf{p}(w|\mathbf{x}_*, \mathbf{X}, \mathbf{y}) \cancel{\mathbf{p}(\mathbf{x}_*, \mathbf{X}, w)} dw}{\mathbf{p}(\mathbf{x}_*, \mathbf{X}, \mathbf{y})} \\ &= \int \mathbf{p}(\mathbf{f}_*|\mathbf{x}_*, \mathbf{X}, \mathbf{y}, w) \mathbf{p}(w|\mathbf{x}_*, \mathbf{X}, \mathbf{y}) dw \\ &\stackrel{\clubsuit}{=} \int \mathbf{p}(\mathbf{f}_*|\mathbf{x}_*, w) \mathbf{p}(w|\mathbf{X}, \mathbf{y}) dw \end{aligned}$$

**Note ♣**

- $\mathbf{f}_*$  is independent of  $\mathcal{D} = \{\mathbf{X}, \mathbf{y}\}$  given the fixed parameter  $w$ .
- $w$  does only depend on the observed data  $\mathcal{D} = \{\mathbf{X}, \mathbf{y}\}$  and not the unseen data  $\mathbf{x}_*$ .

*Proof.* Definition 5.18:

$$\begin{aligned} \mathbf{p}(\mathbf{y}|\mathbf{X}) &= \int \mathbf{p}(\mathbf{y}, w|\mathbf{X}) dw = \int \mathbf{p}(\mathbf{y}|w, \mathbf{X}) \mathbf{p}(w|\mathbf{X}) dw \\ \text{eq. (5.6)} \quad &\int \mathbf{p}(\mathbf{y}|w, \mathbf{X}) \mathbf{p}(w) dw \end{aligned}$$

*Proof.* Definition 6.4:

$$\begin{aligned} \mathbf{p}(\mathbf{x}_t, \mathbf{x}_{t-1}|\mathbf{y}_{1:t_1}) &\stackrel{\text{eq. (21.19)}}{=} \mathbf{p}(\mathbf{x}_t|\mathbf{x}_{t-1}, \mathbf{y}_{1:t_1}) \mathbf{p}(\mathbf{x}_{t-1}|\mathbf{y}_{1:t_1}) \\ &\stackrel{\text{independ.}}{=} \mathbf{p}(\mathbf{x}_t|\mathbf{x}_{t-1}) \mathbf{p}(\mathbf{x}_{t-1}|\mathbf{y}_{1:t_1}) \end{aligned}$$

marginalization/integration over  $\mathbf{x}_{t-1}$  gives the desired result.  $\square$

*Proof.* Definition 6.5:

$$\begin{aligned} \mathbf{p}(\mathbf{x}_t, \mathbf{y}_t|\mathbf{y}_{1:t-1}) &\stackrel{\text{eq. (21.23)}}{=} \begin{cases} \mathbf{p}(\mathbf{x}_t|\mathbf{y}_t, \mathbf{y}_{1:t-1}) \mathbf{p}(\mathbf{y}_t|\mathbf{y}_{1:t-1}) \\ \mathbf{p}(\mathbf{y}_t|\mathbf{x}_t, \mathbf{y}_{1:t-1}) \mathbf{p}(\mathbf{x}_t|\mathbf{y}_{1:t-1}) \end{cases} \\ \mathbf{p}(\mathbf{y}_t|\mathbf{x}_t, \mathbf{y}_{1:t-1}) &\stackrel{\text{corollary 6.2}}{=} \mathbf{p}(\mathbf{y}_t|\mathbf{x}_t) \\ &\dots\dots\dots \\ \text{from which follows immediately eq. (6.5).} \quad &\square \end{aligned}$$

*Proof.* Definition 6.6:

$$\begin{aligned} \mathbf{p}(\mathbf{y}_t|\mathbf{y}_{1:t-1}) &= \int \mathbf{p}(\mathbf{y}_t, \mathbf{x}_t|\mathbf{y}_{1:t-1}) d\mathbf{x}_t \\ &= \int \mathbf{p}(\mathbf{y}_t|\mathbf{x}_t, \mathbf{y}_{1:t-1}) \mathbf{p}(\mathbf{x}_t|\mathbf{y}_{1:t-1}) d\mathbf{x}_t \\ \text{corollary 6.2} \quad &\stackrel{\text{corollary 6.2}}{=} \int \mathbf{p}(\mathbf{y}_t|\mathbf{x}_t) \mathbf{p}(\mathbf{x}_t|\mathbf{y}_{1:t-1}) d\mathbf{x}_t \end{aligned}$$

*Proof.* corollary 6.3:

$$\begin{aligned} \mathbf{p}(\mathbf{x}_{1:t}, \mathbf{y}_{1:t}) &\stackrel{\text{eq. (21.19)}}{=} \mathbf{p}(\mathbf{y}_{1:t}|\mathbf{x}_{1:t}) \mathbf{p}(\mathbf{x}_{1:t}) \\ \text{law 21.2} \quad &\mathbf{p}(\mathbf{y}_{1:t}|\mathbf{x}_{1:t}) \mathbf{p}(\mathbf{x}_t|\mathbf{x}_{t-1:0}) \cdots \mathbf{p}(\mathbf{x}_2|\mathbf{x}_1) \mathbf{p}(\mathbf{x}_1) \\ \text{eq. (6.1)} \quad &\mathbf{p}(\mathbf{y}_{1:t}|\mathbf{x}_{1:t}) \left( \mathbf{p}(\mathbf{x}_1) \prod_{i=1}^t \mathbf{p}(\mathbf{x}_i|\mathbf{x}_{i-1}) \right) \\ \text{law 21.2} \quad &\mathbf{p}(\mathbf{y}_{1:t}|\mathbf{x}_{1:t}) \left( \mathbf{p}(\mathbf{y}_1|\mathbf{x}_1) \cdots \mathbf{p}(\mathbf{y}_t|\mathbf{x}_t) \right) \\ \text{corollary 6.2} \quad &\stackrel{\text{corollary 6.2}}{=} \left( \mathbf{p}(\mathbf{y}_1|\mathbf{x}_1) \cdots \mathbf{p}(\mathbf{y}_t|\mathbf{x}_t) \right) \left( \mathbf{p}(\mathbf{x}_1) \prod_{i=1}^t \mathbf{p}(\mathbf{x}_i|\mathbf{x}_{i-1}) \right) \\ &= \frac{\mathbf{p}(\mathbf{y}_1|\mathbf{x}_1) \mathbf{p}(\mathbf{x}_1)}{\prod_{i=1}^t \mathbf{p}(\mathbf{y}_i|\mathbf{x}_i) \mathbf{p}(\mathbf{x}_i|\mathbf{x}_{i-1})} \end{aligned}$$

*Proof.* [def. 7.1]

$$\begin{aligned} \mathbf{p}(w|\mathcal{D}) &\propto \mathbf{p}(\mathcal{D}|w) \mathbf{p}(w) \\ &\propto \exp \left( -\frac{1}{2} \frac{1}{\sigma_n^2} (\mathbf{y} - \mathbf{X}w)^\top (\mathbf{y} - \mathbf{X}w) \right) \exp \left( -\frac{1}{2} w^\top \Sigma^{-1} w \right) \\ &\propto \exp \left\{ -\frac{1}{2} \frac{1}{\sigma_n^2} (\mathbf{y}^\top \mathbf{y} - 2w^\top \mathbf{X}^\top \mathbf{y} + w^\top \mathbf{X}^\top \mathbf{X}^\top w + \sigma_n^2 w^\top \Sigma^{-1} w) \right\} \\ &\propto \exp \left\{ -\frac{1}{2} \frac{1}{\sigma_n^2} (\mathbf{y}^\top \mathbf{y} - 2w^\top \mathbf{X}^\top \mathbf{y} + \underbrace{w^\top (\mathbf{X}^\top \mathbf{X}^\top + \sigma_n^2 \Sigma^{-1}) w}_{\dots\dots\dots}) \right\} \end{aligned}$$

We know that a Gaussian  $\mathcal{N}(w|\bar{w}, \Sigma_w^{-1})$  should look like:

$$\begin{aligned} \mathbf{p}(w|\mathcal{D}) &\propto \exp \left( -\frac{1}{2} (w - \bar{w})^\top \Sigma_w (w - \bar{w}) \right) \\ &\propto \exp \left( -\frac{1}{2} \left( \underbrace{w^\top \Sigma_w w}_{\dots\dots\dots} - 2w^\top \Sigma_w \bar{w} + \bar{w}^\top \Sigma_w \bar{w} \right) \right) \end{aligned}$$

$\Sigma_w$  follows directly  $\Sigma_w = \sigma_n^{-2} \mathbf{X} \mathbf{X}^\top + \Sigma_p$

$\bar{w}$  follows from  $2w^\top \mathbf{X}^\top \mathbf{y} = 2w^\top \Sigma_w \bar{w} \Rightarrow \bar{w} = \Sigma_w^{-1} \mathbf{X}^\top \mathbf{y}$ .  $\square$

*Proof.* [def. 7.2]

*Proof.* [def. 8.4] In a Bayesian setting we are usually interested in maximizing the log prior/likelihood:

$$\mathcal{L}_n(\theta) = \log(\mathbf{p}(\theta|\mathbf{y})) = (\log \text{Prior} + \log \text{Likelihood})$$

we now approximate  $\mathcal{L}_n(\theta)$  by a Taylor approximation around its maximum  $\hat{\theta}$ :

$$\mathcal{L}_n(\theta) = \mathcal{L}_n(\hat{\theta}) + \frac{1}{2} \frac{\partial^2 \mathcal{L}_n}{\partial \theta^2} \Big|_{\hat{\theta}} (\theta - \hat{\theta})^2 + \mathcal{O}((\theta - \hat{\theta})^3)$$

we can no derive the distribution:

$$\begin{aligned} \mathbf{p}(\theta|\mathbf{y}) &\approx \exp(\mathcal{L}_n(\theta)) = \exp(\log \mathbf{p}(\theta|\mathbf{y})) \\ &= \mathbf{p}(\hat{\theta}) \exp \left( \frac{1}{2} \frac{\partial^2 \mathcal{L}_n}{\partial \theta^2} \Big|_{\hat{\theta}} \right) \\ &= \sqrt{2\pi\sigma^2} \mathbf{p}(\hat{\theta}) \mathcal{N}(\theta; \hat{\theta}, \sigma) \approx \frac{1}{\sqrt{2\pi\sigma^2}} \mathcal{N}(\theta; \hat{\theta}, \sigma) \end{aligned}$$

**Notes**

- the derivative of the maximum must be zero by definition  $\frac{\partial \mathcal{L}_n}{\partial \theta} \Big|_{\hat{\theta}} = 0$
- we approximate the normalization constant  $\frac{1}{Z}$  by  $\sqrt{2\pi\sigma^2} \mathbf{p}(\hat{\theta})$ .

*Proof.* [def. 8.4] 2D:

$$\begin{aligned} \nabla \mathcal{L}_n(\theta) &= \nabla \mathcal{L}_n(\theta_1, \theta_2) = 0 \\ \mathcal{L}_n(\theta) &= \mathcal{L}_n(\hat{\theta}) + \frac{1}{2} (A(\theta_1 - \hat{\theta}_1)^2 + B(\theta_2 - \hat{\theta}_2)^2 + C(\theta_1 - \hat{\theta}_1)(\theta_2 - \hat{\theta}_2)) \\ \mathcal{L}_n(\theta) &= \mathcal{L}_n(\hat{\theta}) + (\theta - \hat{\theta})^\top H(\hat{\theta}) (\theta - \hat{\theta}) \\ &= \mathcal{L}_n(\hat{\theta}) + \frac{1}{2} Q(\theta) \\ A &= \frac{\partial^2 \mathcal{L}_n}{\partial \theta^2} \Big|_{\hat{\theta}} \quad B = \frac{\partial^2 \mathcal{L}_n}{\partial \theta^2} \Big|_{\hat{\theta}} \quad C = \frac{\partial^2 \mathcal{L}_n}{\partial \theta_1 \partial \theta_2} \Big|_{\hat{\theta}} \\ H &= \begin{bmatrix} A & C \\ C & B \end{bmatrix} \quad \Sigma = H^{-1}(\hat{\theta}) \end{aligned}$$

*Proof.* [def. 8.4]  $k$ -dimensional:

$$\begin{aligned} \mathcal{L}_n(\theta) &\approx \mathcal{L}_n(\hat{\theta}) + (\theta - \hat{\theta})^\top \nabla \nabla^\top \mathcal{L}_n(\hat{\theta}) (\theta - \hat{\theta}) \\ H(\theta) &= \nabla \nabla^\top \mathcal{L}_n(\theta) \quad \Sigma = H^{-1}(\hat{\theta}) \\ \mathbf{p}(\theta|\mathbf{y}) &= \sqrt{(2\pi)^n \det(\Sigma)} \mathbf{p}(\hat{\theta}) \mathcal{N}(\theta; \hat{\theta}, \Sigma) \\ &\approx c \frac{1}{\sqrt{(2\pi)^n \det(\Sigma)}} \mathcal{N}(\theta; \hat{\theta}, \Sigma) \end{aligned}$$

*Proof.* [def. 8.5]

$$\begin{aligned} q^* &\in \arg \min_{q \in \mathcal{Q}} \text{KL}(q(\theta) \parallel \mathbf{p}(\theta|\mathbf{y})) \\ \mathbf{p}(\theta|\mathbf{y}) &= \frac{1}{Z} \mathbf{p}(\theta, \mathbf{y}) \\ &= \arg \min_q \mathbb{E}_{\theta \sim q} \left[ \log \frac{q(\theta)}{\frac{1}{Z} \mathbf{p}(\theta, \mathbf{y})} \right] \\ &= \arg \min_q \mathbb{E}_{\theta \sim q} \left[ \log q(\theta) - \log \frac{1}{Z} - \log \mathbf{p}(\theta, \mathbf{y}) \right] \\ &= \arg \min_q \mathbb{E}_{\theta \sim q} \left[ -\underbrace{[\log q(\theta)]}_{H(q)} + \cancel{\mathbb{E}_{\theta \sim q} [\log Z]} \right. \\ &\quad \left. - \mathbb{E}_{\theta \sim q} [\log \mathbf{p}(\theta, \mathbf{y})] \right] \\ &= \arg \max_q \mathbb{E}_{\theta \sim q} [\log \mathbf{p}(\theta, \mathbf{y})] + H(q) \\ &= \arg \max_q \mathbb{E}_{\theta \sim q} [\log \mathbf{p}(\theta|\mathbf{y}) + \log \mathbf{p}(\theta) - \log q(\theta)] \\ &= \arg \max_q \mathbb{E}_{\theta \sim q} [\log \mathbf{p}(\theta|\mathbf{y})] + \text{KL}(q(\theta) \parallel \mathbf{p}(\theta)) \end{aligned}$$

*Proof.* [def. 8.6]

$$\begin{aligned} \log \mathbf{p}(\mathbf{y}) &= \log \int \mathbf{p}(\mathbf{y}, \theta) d\theta = \log \int \mathbf{p}(\mathbf{y}|\theta) \mathbf{p}(\theta) d\theta \\ &= \log \int \mathbf{p}(\mathbf{y}|\theta) \frac{\mathbf{p}(\theta)}{q_\lambda(\theta)} q_\lambda(\theta) d\theta \\ &= \log \mathbb{E}_{\theta \sim q_\lambda} \left[ \mathbf{p}(\mathbf{y}|\theta) \frac{\mathbf{p}(\theta)}{q_\lambda(\theta)} \right] \\ \text{eq. (21.54)} \quad &\geq \mathbb{E}_{\theta \sim q_\lambda} \left[ \log \left( \mathbf{p}(\mathbf{y}|\theta) \frac{\mathbf{p}(\theta)}{q_\lambda(\theta)} \right) \right] \\ &= \mathbb{E}_{\theta \sim q_\lambda} \left[ \log \mathbf{p}(\mathbf{y}|\theta) - \log \frac{\mathbf{p}(\theta)}{q_\lambda(\theta)} \right] \\ &= \mathbb{E}_{\theta \sim q_\lambda} [\log \mathbf{p}(\mathbf{y}|\theta)] - \text{KL}(q_\lambda \parallel \mathbf{p}(\cdot)) \end{aligned}$$

*Proof.* principle 8.2 Let:

$$\begin{aligned} \epsilon \sim \phi(\epsilon) \quad \theta = g(\epsilon; \lambda) &\text{ correspond to } \begin{aligned} X &\sim f_X \\ \mathcal{Y} &= \{y|y = g(x), \forall x \in \mathcal{X}\} \end{aligned} \end{aligned}$$

then it follows immediately with eq. (21.46):

$$\begin{aligned} \theta \sim q_\lambda(\theta) = q(\theta|\lambda) &= \frac{f_X(g^{-1}(y))}{\left| \frac{dg}{dx}(g^{-1}(y)) \right|} \\ &= \phi(\epsilon) |\nabla_\epsilon g(\epsilon; \lambda)|^{-1} \end{aligned}$$

$\Rightarrow$  parameterized in terms of  $\epsilon$   $\square$

*Proof.* [def. 8.12]

$$\begin{aligned} \theta_{t+1} &= \theta_t - \eta_t \left( \nabla \log \mathbf{p}(\theta) - \nabla \sum_{i=1}^n \log \mathbf{p}(y_i|\mathbf{x}_i, \theta) \right) \\ &= \theta_t - \eta_t \left( 2\lambda \theta_t - \nabla \sum_{i=1}^n \log \mathbf{p}(y_i|\mathbf{x}_i, \theta) \right) \\ &= \theta_t (1 - 2\lambda \eta_t) - \eta_t \nabla \sum_{i=1}^n \log \mathbf{p}(y_i|\mathbf{x}_i, \theta) \end{aligned}$$

## 5. Examples

**Example 8.1 Laplace Approximation  
Logistic Regression Likelihood + Gaussian Prior:**

**Example 8.2 ELBO Bayesian Logistic Regression:** Suppose:

$$\begin{aligned} Q &= \text{diag. Gaussians} \Rightarrow \lambda = \begin{bmatrix} \mu_{1:d} & \sigma_{1:d}^2 \end{bmatrix} \in \mathbb{R}^{2d} \\ \mathbf{p}(\theta) &= \mathcal{N}(0, I) \end{aligned}$$

Then it follows for the terms of the ELBO:

$$\begin{aligned} \text{KL}(q_\lambda \parallel \mathbf{p}(\theta)) &= \frac{1}{2} \sum_{i=1}^d \left( \mu_i^2 + \sigma_i^2 - 1 - \ln \sigma_i^2 \right) \\ \mathbb{E}_{\theta \sim q_\lambda} [\mathbf{p}(y|\theta)] &= \mathbb{E}_{\theta \sim q_\lambda} \left[ \sum_{i=1}^n \log \mathbf{p}(y_i|\theta, \mathbf{x}_i) \right] \\ &= \mathbb{E}_{\theta \sim q_\lambda} \left[ -\sum_{i=1}^n \log(1 + \exp(-y_i \theta^\top \mathbf{x}_i)) \right] \end{aligned}$$

**Example 8.3 ELBO Gradient Gaussian:** Suppose:

$$\begin{aligned} \theta \sim q(\theta|\lambda) &= \mathcal{N}(\theta; \mu, \Sigma) \Rightarrow \lambda = \begin{bmatrix} \mu & \Sigma \end{bmatrix} \\ \epsilon \sim \phi(\epsilon) &= \mathcal{N}(\epsilon; 0, I) \end{aligned}$$

we can reparameterize using principle 8.2 by using:

$$\theta \sim g(\epsilon, \lambda) = C\epsilon + \mu \quad \text{with} \quad C : CC^\top = \Sigma$$

from this it follows: ( $C$  is the Cholesky factor of  $\Sigma$ )

$$g^{-1}(\theta, \lambda) = \epsilon = C^{-1}(\theta - \mu) \quad \frac{\partial g(\epsilon; \lambda)}{\partial \epsilon} = C$$

from this it follows:

$$\begin{aligned} q(\theta|\lambda) &= \frac{\phi(\epsilon)}{\left| \frac{dg(\epsilon; \theta)}{d\epsilon} (g^{-1}(\theta)) \right|} = \phi(\epsilon) |C|^{-1} \\ &\iff \phi(\epsilon) = q(\theta|\lambda) |C| \end{aligned}$$

we can then write the reparameterized expectation part of the gradient of the ELBO as:

$$\begin{aligned} \nabla_\lambda L(\lambda)_1 &= \nabla_\lambda \mathbb{E}_{\epsilon \sim \phi} [\log \mathbf{p}(y|g(\epsilon; \lambda))] \\ &= \nabla_{C, \mu} \mathbb{E}_{\epsilon \sim \mathcal{N}(0, I)} [\log \mathbf{p}(y|C\epsilon + \mu)] \\ &\stackrel{\text{i.i.d.}}{=} \nabla_{C, \mu} \mathbb{E}_{\epsilon \sim \mathcal{N}(0, I)} \left[ \sum_{i=1}^n \log \mathbf{p}(y_i|C\epsilon + \mu, \mathbf{x}_i) \right] \\ &= \nabla_{C, \mu} \mathbb{E}_{\epsilon \sim \mathcal{N}(0, I)} \left[ n \frac{1}{n} \sum_{i=1}^n \log \mathbf{p}(y_i|C\epsilon + \mu, \mathbf{x}_i) \right] \\ &= \nabla_{C, \mu} n \mathbb{E}_{\epsilon \sim \mathcal{N}(0, I)} \left[ \mathbb{E}_{i \sim \mathcal{U}(\{1, n\})} \log \mathbf{p}(y_i|C\epsilon + \mu, \mathbf{x}_i) \right] \\ \text{Draw a mini batch } &\left\{ \epsilon^{(1)}, \dots, \epsilon^{(m)} \right\}_{j=1, \dots, m} \sim \mathcal{U}(\{1, n\}) \\ &= n \frac{1}{m} \sum_{j=1}^m \nabla_{C, \mu} \log \mathbf{p}(y_j|C\epsilon + \mu, \mathbf{x}_j) \\ \nabla_\lambda L(\lambda) &= \nabla_\lambda \text{ELBO}(\lambda) = \mathbb{E}_{\epsilon \sim \mathcal{N}(0, I)} [\nabla_{C, \mu} \log \mathbf{p}(y|C\epsilon + \mu)] \\ &\quad - \nabla_{C, \mu} (q_{C, \mu} \parallel \mathbf{p}(\theta)) \end{aligned}$$

**Example 8.4 BNN Likelihood Function Examples:**

$$\mathbf{p}(y|\mathbf{X}, \theta) = \begin{cases} \mathcal{N}(y; F(\mathbf{X}, \theta), \sigma^2) \\ \mathcal{N}(y; F(\mathbf{X}, \theta)_1, \exp F(\mathbf{X}, \theta)_1) \end{cases}$$

# Kernels

**Given** objects we cannot assume that they are vectors/can be represented as vectors in feature space.  
**Hence** it is also not guaranteed that those objects can be added and multiplied by scalars.  
**Question:** then how can we define a more general notion of similarity?

**Definition 9.1 Similarity Measure**  $\text{sim}(A, B)$ : A similarity measure or similarity function is a real-valued function that quantifies the similarity between two objects.  
No single definition of a similarity measure exists but often they are defined in terms of the inverse of distance metrics and they take on large values for similar objects and either zero or a negative value for very dissimilar objects.

**Definition 9.2 Dissimilarity Measure**  $\text{dissim}(A, B)$ : Is a measure of how dissimilar objects are, rather than how similar they are.  
Thus it takes the largest values for objects that are really far apart from another.  
Dissimilarities are often chosen as the squared norm of two difference vectors:

$$\|\mathbf{x} - \mathbf{y}\|^2 = \mathbf{x}^\top \mathbf{x} + \mathbf{y}^\top \mathbf{y} - 2\mathbf{x}^\top \mathbf{y} \quad \forall \mathbf{x}, \mathbf{y} \in \mathbb{R}^d \quad (9.1)$$
$$\text{dissim}(\mathbf{x}, \mathbf{y}) = \text{sim}(\mathbf{x}, \mathbf{x}) + \text{sim}(\mathbf{y}, \mathbf{y}) - 2\text{sim}(\mathbf{x}, \mathbf{y})$$

## Attention

It is better to rely on similarity measures instead of dissimilarity measures. Dissimilarities are often not adequate from a modeling point of view, because for objects that are really dissimilar/far from each other, we usually have the biggest problem to estimate their distance.  
E.g. for a bag of words it is easy to determine similar words, but it is hard to estimate which words are most dissimilar. For normed vectors the only information of a dissimilarity defined as in eq. (9.1) becomes

$$2\mathbf{x}^\top \mathbf{y} = 2\text{dissim}(\mathbf{x}, \mathbf{y})$$

**Definition 9.3 Feature Map**  $\phi$ : is a mapping  $\phi: \mathcal{X} \mapsto \mathcal{Y}$  that takes an input  $\mathbf{x} \in \mathcal{X} \subseteq \mathbb{R}^d$  and maps it into another feature space  $\mathcal{Y} \subseteq \mathbb{R}^D$ .

## Note

Such feature maps can lead to an exponential number of terms i.e. for a polynomial feature map, with monomials of degree up to  $p$  and feature vectors of dimension  $\mathbf{x} \in \mathbb{R}^d$  we obtain a feature space of size:

$$D = \dim(\mathcal{Y}) = \binom{p+d}{d} = \mathcal{O}(d^p) \quad (9.2)$$

when using the polynomial kernel<sup>[def. 9.10]</sup>, this can be reduced to the order  $d$ .

**Definition 9.4 Kernel k:** Let  $\mathcal{X} \subseteq \mathbb{R}^d$  be the data space. A map  $\mathbf{k}: \mathcal{X} \times \mathcal{X} \mapsto \mathbb{R}$  is called kernel if there exists an inner product space<sup>[def. 16.19]</sup> called **feature space**  $(\mathcal{Y}, \langle \cdot, \cdot \rangle_{\mathcal{Y}})$  and a map  $\phi: \mathcal{X} \mapsto \mathcal{Y}$  s.t.

$$\mathbf{k}(\mathbf{x}, \mathbf{y}) = \langle \phi(\mathbf{x}), \phi(\mathbf{y}) \rangle_{\mathcal{Y}} \quad \forall \mathbf{x}, \mathbf{y} \in \mathcal{X} \quad (9.3)$$

**Corollary 9.1 Kernels and similarity:** Kernels are defined in terms of inner product spaces and hence they have a notion of similarity between their arguments.

## Example

Let  $\mathbf{k}(\mathbf{x}, \mathbf{y}) := \mathbf{x}^\top \mathbf{A} \mathbf{y}$  thus the kernel measures the similarity between  $\mathbf{x}$  and  $\mathbf{y}$  by the inner product  $\mathbf{x}^\top \mathbf{y}$  weighted by the matrix  $\mathbf{A}$ .

**Corollary 9.2 Kernels and distance:** Let  $\mathbf{k}(\mathbf{x}, \mathbf{y})$  be a measure of similarity between  $\mathbf{x}$  and  $\mathbf{y}$  then  $\mathbf{k}$  induces a dissimilarity/distance between  $\mathbf{x}$  and  $\mathbf{y}$  defined as the difference between the self-similarities  $\mathbf{k}(\mathbf{x}, \mathbf{x}) + \mathbf{k}(\mathbf{y}, \mathbf{y})$  and the cross-similarities  $\mathbf{k}(\mathbf{x}, \mathbf{y})$ :

$$\text{dissimilarity}(\mathbf{x}, \mathbf{y}) := \mathbf{k}(\mathbf{x}, \mathbf{x}) + \mathbf{k}(\mathbf{y}, \mathbf{y}) - 2\mathbf{k}(\mathbf{x}, \mathbf{y})$$

## Note

The factor 2 is required to ensure that  $d(\mathbf{x}, \mathbf{x}) = 0$ .

## 1. The Gram Matrix

### Definition 9.5 Kernel (Gram) Matrix:

**Given:** a mapping  $\phi: \mathbb{R}^d \mapsto \mathbb{R}^D$  and a corresponding kernel function  $\mathbf{k}: \mathcal{X} \times \mathcal{X} \mapsto \mathbb{R}$  with  $\mathcal{X} \subseteq \mathbb{R}^d$ .  
**Let**  $S$  be any finite subset of data  $S = \{\mathbf{x}_1, \dots, \mathbf{x}_n\} \subseteq \mathcal{X}$ .  
Then the kernel matrix  $\mathcal{K} \in \mathbb{R}^{n \times n}$  is defined by:

$$\mathcal{K} = \phi(\mathbf{X})\phi(\mathbf{X})^\top = (\phi(\mathbf{x}_1), \dots, \phi(\mathbf{x}_n))(\phi(\mathbf{x}_1), \dots, \phi(\mathbf{x}_n))^\top$$
$$= \begin{pmatrix} \mathbf{k}(\mathbf{x}_1, \mathbf{x}_1) & \dots & \mathbf{k}(\mathbf{x}_1, \mathbf{x}_n) \\ \vdots & \ddots & \vdots \\ \mathbf{k}(\mathbf{x}_n, \mathbf{x}_1) & \dots & \mathbf{k}(\mathbf{x}_n, \mathbf{x}_n) \end{pmatrix} = \begin{pmatrix} \phi(\mathbf{x}_1)^\top \phi(\mathbf{x}_1) & \dots & \phi(\mathbf{x}_1)^\top \phi(\mathbf{x}_n) \\ \vdots & \ddots & \vdots \\ \phi(\mathbf{x}_n)^\top \phi(\mathbf{x}_1) & \dots & \phi(\mathbf{x}_n)^\top \phi(\mathbf{x}_n) \end{pmatrix}$$
$$\mathcal{K}_{ij} = \mathbf{k}(\mathbf{x}_i, \mathbf{x}_j) = \phi(\mathbf{x}_i)^\top \phi(\mathbf{x}_j)$$

### Corollary 9.3

**Kernel Eigenvector Decomposition:**  
For any symmetric matrix (Gram matrix  $\mathcal{K}(\mathbf{x}_i, \mathbf{x}_j)_{i,j=1}^n$ ) there exists an eigenvector decomposition:

$$\mathcal{K} = \mathbf{V} \mathbf{\Lambda} \mathbf{V}^\top \quad \mathbf{V} \mathbf{\Lambda} \mathbf{V}^\top$$

$\mathbf{V}$ : orthogonal matrix of eigenvectors  $(\mathbf{v}_{t,i})_{i=1}^n$   
 $\mathbf{\Lambda}$ : diagonal matrix of eigenvalues  $\lambda_i$

**Assuming** all eigenvalues  $\lambda_t$  are non-negative, we can calculate the mapping:

$$\phi: \mathbf{x}_i \mapsto \left( \sqrt{\lambda_t} \mathbf{v}_{t,i} \right)_{t=1}^n \in \mathbb{R}^n, \quad i = 1, \dots, n \quad (9.5)$$

which allows us to define the Kernel  $\mathcal{K}$  as:

$$\phi^\top(\mathbf{x}_i) \phi(\mathbf{x}_j) = \sum_{t=1}^n \lambda_t \mathbf{v}_{t,i} \mathbf{v}_{t,j} = (\mathbf{V} \mathbf{\Lambda} \mathbf{V}^\top)_{i,j} = \mathcal{K}(\mathbf{x}_i, \mathbf{x}_j) \quad (9.6)$$

### 1.1. Necessary Properties

#### Property 9.1 Inner Product Space:

$\mathbf{k}$  must be an *inner product* of a suitable space  $\mathcal{Y}$ .

#### Property 9.2 Symmetry: $\mathbf{k}/\mathcal{K}$ must be symmetric:

$$\mathbf{k}(\mathbf{x}, \mathbf{y}) = \mathbf{k}(\mathbf{y}, \mathbf{x}) = \phi(\mathbf{x})^\top \phi(\mathbf{y}) = \phi(\mathbf{y})^\top \phi(\mathbf{x}) \quad \forall \mathbf{x}, \mathbf{y} \in \mathcal{X}$$

**Property 9.3 Non-negative Eigenvalues/p.s.d.s Form:**  
Let  $S = \{\mathbf{x}_1, \dots, \mathbf{x}_n\}$  be an  $n$ -set of a *finite* input space  $\mathcal{Y}$ . A kernel  $\mathbf{k}$  must induce a *p.s.d. symmetric* kernel matrix  $\mathbf{k}$  for any possible  $S \subseteq \mathcal{X}$  see section 1.

$\iff$  all eigenvalues of the kernel gram matrix  $\mathcal{K}$  for *finite*  $\mathcal{Y}$  must be non-negative corollary 16.2.

## Notes

- The extension to infinite dimensional Hilbert Spaces might also include a non-negative weighting/eigenvalues:

$$\langle \phi(\mathbf{x}), \phi(\mathbf{z}) \rangle = \sum_{i=1}^{\infty} \lambda_i \phi_i(\mathbf{x}) \phi_i(\mathbf{z})$$

- In order to be able to use a kernel, we need to verify that the kernel is **p.s.d.** for all  $n$ -vectors  $\mathcal{X} = \{\mathbf{x}_1, \dots, \mathbf{x}_n\}$ , as well as for future unseen values.

## 2. Mercers Theorem

**Theorem 9.1 Mercers Theorem:** Let  $\mathcal{X}$  be a compact subset of  $\mathbb{R}^n$  and  $\mathbf{k}: \mathcal{X} \times \mathcal{X} \mapsto \mathbb{R}$  a **kernel function**.

**Then** one can expand  $\mathbf{k}$  in a uniformly convergent series of bounded functions  $\phi$  s.t.

$$\mathbf{k}(\mathbf{x}, \mathbf{x}') = \sum_{i=1}^{\infty} \lambda \phi_i(\mathbf{x}) \phi_i(\mathbf{x}') \quad (9.7)$$

**Theorem 9.2 General Mercers Theorem:** Let  $\Omega$  be a compact subset of  $\mathbb{R}^n$ . Suppose  $\mathbf{k}$  is a general continuous symmetric function such that the integral operator:

$$T_{\mathbf{k}}: L_2(\mathcal{X}) \mapsto L_2(\mathcal{X}) \quad (T_{\mathbf{k}} f)(\cdot) = \int_{\Omega} \mathbf{k}(\cdot, \mathbf{x}) f(\mathbf{x}) d\mathbf{x} \quad (9.8)$$

is **positive**, that is it satisfies:

$$\int_{\Omega \times \Omega} \mathbf{k}(\mathbf{x}, \mathbf{z}) f(\mathbf{x}) f(\mathbf{z}) d\mathbf{x} d\mathbf{z} > 0 \quad \forall f \in L_2(\Omega)$$

**Then** we can expand  $\mathbf{k}(\mathbf{x}, \mathbf{z})$  in a uniformly convergent series in terms of  $T_{\mathbf{k}}$ 's eigen-functions  $\phi_j \in L_2(\Omega)$ , with  $\|\phi_j\|_{L_2} = 1$  and **positive** associated eigenvalues  $\lambda_j > 0$ .

## Note

All kernels satisfying Mercers conditions describe an inner product in a high dimensional space.  
 $\implies$  can replace the inner product by the kernel function.

Check if  $\mathbb{R}$  or  $\mathbb{R}^+$  as in script

## 3. The Kernel Trick

**Definition 9.6 Kernel Trick:** If a kernel has an analytic form we do no longer need to calculate:

- the function mapping  $\mathbf{x} \mapsto \phi(\mathbf{x})$  and
- the inner product  $\phi(\mathbf{x})^\top \phi(\mathbf{y})$

explicitly but simply use the formula for the kernel:

$$\phi(\mathbf{x})^\top \phi(\mathbf{x}) = \mathbf{k}(\mathbf{x}, \mathbf{y}) \quad (9.9)$$

see examples 9.1 and 9.2

## Note

- Possible to operate in any  $n$ -dimensional function space, efficiently.
- $\phi$  not necessary anymore.
- Complexity independent of the functions space.

## 4. Types of Kernels

### 4.1. Stationary Kernels

**Definition 9.7 Stationary Kernel:** A stationary kernel is a kernel that only considers vector differences:

$$\mathbf{k}(\mathbf{x}, \mathbf{y}) = \mathbf{k}(\mathbf{x} - \mathbf{y}) \quad (9.10)$$

see example 9.3

### 4.2. Isotropic Kernels

**Definition 9.8 Isotropic Kernel:** A isotropic kernel is a kernel that only considers distance differences:

$$\mathbf{k}(\mathbf{x}, \mathbf{y}) = \mathbf{k}(\|\mathbf{x} - \mathbf{y}\|_2) \quad (9.11)$$

### Corollary 9.4 :

$$\text{Isotropic} \quad \rightarrow \quad \text{Stationary}$$

## 5. Important Kernels on $\mathbb{R}^d$

### 5.1. The Linear Kernel

**Definition 9.9 Linear/String Kernel:**

$$\mathbf{k}(\mathbf{x}, \mathbf{y}) = \mathbf{x}^\top \mathbf{y} \quad (9.12)$$

### 5.2. The Polynomial Kernel

**Definition 9.10 Polynomial Kernel:** represents all monomials<sup>[def. 13.2]</sup> of degree up to  $m$

$$\mathbf{k}(\mathbf{x}, \mathbf{y}) = (1 + \mathbf{x}^\top \mathbf{y})^m \quad (9.13)$$

### 5.3. The Sigmoid Kernel

**Definition 9.11 Sigmoid/tanh Kernel:**

$$\mathbf{k}(\mathbf{x}, \mathbf{y}) = \tanh(\kappa \mathbf{x}^\top \mathbf{y} - b) \quad (9.14)$$

### 5.4. The Exponential Kernel

**Definition 9.12 Exponential Kernel:** is a continuous kernel that is non-differential  $\mathbf{k} \in C^0$ :

$$\mathbf{k}(\mathbf{x}, \mathbf{y}) = \exp\left(-\frac{\|\mathbf{x} - \mathbf{y}\|_1}{\theta}\right) \quad (9.15)$$

$\theta \in \mathbb{R}$ : corresponds to a threshold.

### 5.5. The Gaussian Kernel

**Definition 9.13 Gaussian/Squared Exp. Kernel/Radial Basis Functions (RBF):**

Is an infinite dimensional smooth kernel  $\mathbf{k} \in C^\infty$  with some useful properties

$$\mathbf{k}(\mathbf{x}, \mathbf{y}) = \exp\left(-\frac{\|\mathbf{x} - \mathbf{y}\|^2}{2\theta^2}\right) \approx \begin{cases} 1 & \text{if } \mathbf{x} \text{ and } \mathbf{y} \text{ close} \\ 0 & \text{if } \mathbf{x} \text{ and } \mathbf{y} \text{ far away} \end{cases} \quad (9.16)$$

**Explanation 9.1** (Threshold  $\theta$ ).  $2\theta \in \mathbb{R}$  corresponds to a threshold that determines how close input values need to be in order to be considered similar:

$$\mathbf{k} = \exp\left(-\frac{\text{dist}^2}{2\theta^2}\right) \approx \begin{cases} 1 \iff \text{sim} & \text{if } \text{dist} \ll \theta \\ 0 \iff \text{dissim} & \text{if } \text{dist} \gg \theta \end{cases}$$

or in other words how much we believe in our data i.e. for smaller length scale we do trust our data less and the admissible functions vary much more.

## Note

If we chose  $h$  small, all data points not close to  $h$  will be 0/discarded  $\iff$  data points are considered as independent. Length of all vectors in **feature space** is one  $\mathbf{k}(\mathbf{x}, \mathbf{x}) = e^0 = 1$ .  
**Thus:** Data points in input space are projected onto a high-(infinite)-dimensional sphere in feature space.  
**Classification:** Cutting with hyperplanes through the sphere. **How to choose  $h$ :** good heuristics, take median of the distance all points but better is cross validation.

## 5.6. The Matern Kernel

When looking at actual data/sample paths the smoothness of the Gaussian kernel<sup>[def. 9.13]</sup> is often a too strong assumption that does not model reality the same holds true for the non-smoothness of the exponential kernel<sup>[def. 9.12]</sup>. A solution to this dilemma is the Matern kernel.

**Definition 9.14 Matern Kernel:** is a kernel which allows you to specify the level of smoothness  $\mathbf{k} \in C^{[\nu]}$  by a positive parameter  $\nu$ :

$$\mathbf{k}(\mathbf{x}, \mathbf{y}) = \frac{2^{1-\nu}}{\Gamma(\nu)} \left( \frac{\sqrt{2\nu} \|\mathbf{x} - \mathbf{y}\|_2}{\rho} \right)^\nu \mathcal{K}_\nu \left( \frac{\sqrt{2\nu} \|\mathbf{x} - \mathbf{y}\|_2}{\rho} \right) \quad (9.17)$$

$\nu, \rho \in \mathbb{R}_+$   
 $\mathcal{K}_\nu$  modified Bessel function of the second kind

## 6. Kernel Engineering

Often linear and even non-linear simple kernels are not sufficient to solve certain problems, especially for pairwise problems i.e. user & product, exon & intron, ...  
Composite kernels can be the solution to such problems.

### 6.1. Closure Properties/Composite Rules

**Suppose** we have two kernels:

$$\mathbf{k}_1: \mathcal{X} \times \mathcal{X} \mapsto \mathbb{R} \quad \mathbf{k}_2: \mathcal{X} \times \mathcal{X} \mapsto \mathbb{R}$$

defined on the data space  $\mathcal{X} \subseteq \mathbb{R}^d$ . Then we may define using Composite Rules:

$$\mathbf{k}(\mathbf{x}, \mathbf{x}') = \mathbf{k}_1(\mathbf{x}, \mathbf{x}') + \mathbf{k}_2(\mathbf{x}, \mathbf{x}') \quad (9.18)$$

$$\mathbf{k}(\mathbf{x}, \mathbf{x}') = \mathbf{k}_1(\mathbf{x}, \mathbf{x}') \cdot \mathbf{k}_2(\mathbf{x}, \mathbf{x}') \quad (9.19)$$

$$\mathbf{k}(\mathbf{x}, \mathbf{x}') = \alpha \mathbf{k}_1(\mathbf{x}, \mathbf{x}') \quad \alpha \in \mathbb{R}_+ \quad (9.20)$$

$$\mathbf{k}(\mathbf{x}, \mathbf{x}') = f(\mathbf{x}) f(\mathbf{x}') \quad (9.21)$$

$$\mathbf{k}(\mathbf{x}, \mathbf{x}') = \mathbf{k}_3(\phi(\mathbf{x}), \phi(\mathbf{x}')) \quad (9.22)$$

$$\mathbf{k}(\mathbf{x}, \mathbf{x}') = p(\mathbf{k}(\mathbf{x}, \mathbf{x}')) \quad (9.23)$$

$$\mathbf{k}(\mathbf{x}, \mathbf{x}') = \exp(\mathbf{k}(\mathbf{x}, \mathbf{x}')) \quad (9.24)$$

**Where**

$f: \mathcal{X} \mapsto \mathbb{R}$	a real valued function
$\mathbf{p}: \mathcal{X} \mapsto \mathbb{R}^e$	the explicit mapping
$\mathbf{p}$	a polynomial with pos. coefficients
$\mathbf{k}_3$	a Kernel over $\mathbb{R}^e \times \mathbb{R}^e$

## Proofs

*Proof.* Property 9.3 The kernel matrix is positive-semidefinite:

**Let**  $\phi: \mathcal{X} \mapsto \mathbb{R}^d$  and  $\Phi = [\phi(\mathbf{x}_1) \dots \phi(\mathbf{x}_n)]^\top \in \mathbb{R}^{d \times n}$ .

**Thus:**  $\mathcal{K} = \Phi^\top \Phi \in \mathbb{R}^{n \times n}$ .

$$\mathbf{v}^\top \mathcal{K} \mathbf{v} = \mathbf{v}^\top \Phi^\top \Phi \mathbf{v} = (\Phi \mathbf{v})^\top \Phi \mathbf{v} = \|\Phi \mathbf{v}\|_2^2 \geq 0$$

□

Examples

**Example 9.1** Calculating the Kernel by hand:

Let :

$$\boldsymbol{x} = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}$$

$$\phi(\boldsymbol{x}) \mapsto \{x_1^2, x_2^2, \sqrt{2}x_1, x_2\}$$
$$\phi : \mathbb{R}^{d=2} \mapsto \mathbb{R}^{D=3}$$

We can now have a decision boundary in this 3-D feature space  $\mathcal{Y}$  of  $\phi$  as:

$$\beta_0 + \beta_1 x_1^2 + \beta_2 x_2^2 + \beta_3 \sqrt{2}x_1 x_2 = 0$$
$$\left\langle \phi(\boldsymbol{x}^{(i)}), \phi(\boldsymbol{x}^{(j)}) \right\rangle$$
$$= \left\langle \left\{x_{i1}^2, x_{i2}^2, \sqrt{2}x_{i1}, x_{i2}\right\}, \left\{x_{j1}^2, x_{j2}^2, \sqrt{2}x_{j1}, x_{j2}\right\} \right\rangle$$
$$= x_{i1}^2 x_{j1}^2 + x_{i2}^2 x_{j2}^2 + 2x_{i1} x_{i2} x_{j1} x_{j2}$$

Operation Count:

- 2 · 3 operations to map  $\boldsymbol{x}_i$  and  $\boldsymbol{x}_j$  into the 3D space  $\mathcal{Y}$ .
- Calculating an inner product of  $\langle \phi(\boldsymbol{x}^{(i)}), \phi(\boldsymbol{x}^{(j)}) \rangle$  with 3 additional operations.

**Example 9.2**

Calculating the Kernel using the Kernel Trick:

$$\left\langle \phi(\boldsymbol{x}^{(i)}), \phi(\boldsymbol{x}^{(j)}) \right\rangle = \underbrace{\langle \boldsymbol{x}_i, \boldsymbol{x}_j \rangle^2}_{:= \mathbf{k}(\boldsymbol{x}_i, \boldsymbol{x}_j)} = \langle \{x_{i1}, x_{i2}\}, \{x_{i1}, x_{i2}\} \rangle^2$$
$$= (x_{i1} x_{i2} + x_{j1} x_{j2})^2$$
$$= x_{i1}^2 x_{j1}^2 + x_{i2}^2 x_{j2}^2 + 2x_{i1} x_{i2} x_{j1} x_{j2}$$

Operation Count:

- 2 multiplicaitons of  $x_{i1} x_{j1}$  and  $x_{i2} x_{j2}$ .
- 1 operation for taking the square of a scalar.

Conclusion

The Kernel trick needed only 3 in comparison to 9 operations.

**Example 9.3** Stationary Kernels:

$$\mathbf{k}(\boldsymbol{x}, \boldsymbol{y}) = \exp \left( \frac{(\boldsymbol{x} - \boldsymbol{y})^\top M (\boldsymbol{x} - \boldsymbol{y})}{h^2} \right)$$

is a stationary but not an isotropic kernel.

Math Appendix

Logic  
Set Theory

<b>Definition 11.1 Set</b> $A = \{1, 3, 2\}$ : is a well-defined group of distinct items that are considered as an object in its own right. The arrangement/order of the objects does not matter but each member of the set must be unique.
<b>Definition 11.2 Empty Set</b> $\{\}$ / $\emptyset$ : is the unique set having no elements/cardinality <sup>[def. 11.4]</sup> zero.
<b>Definition 11.3 Multiset/Bag</b> : Is a set-like object in which multiplicity matters, that is we can have multiple elements of the same type. I.e. $\{1, 1, 2, 3\} \neq \{1, 2, 3\}$
<b>Definition 11.4 Cardinality</b> $ S $ : Is the number of elements that are contained in a set.
<b>Definition 11.5 The Power Set</b> $\mathcal{P}(S)/2^S$ : The power set of any set $S$ is the set of all subsets of S, including the empty set and $S$ itself. The cardinality of the power set is $2^S$ is equal to $2^{ S }$ .
<b>Definition 11.6 Closure</b> : A set is <i>closed</i> under an operation $\Omega$ if performance of that operations onto members of the set always produces a member of that set.

1. Number Sets

1.1. The Real Numbers  $\mathbb{R}$   
1.1.1. Intervals

<b>Definition 11.7 Closed Interval</b> $[a, b]$ : The closed interval of $a$ and $b$ is the set of all real numbers that are within $a$ and $b$ , including $a$ and $b$ : $[a, b] = \{x \in \mathbb{R} \mid a \leq x \leq b\}$ (11.1)
<b>Definition 11.8 Open Interval</b> $(a, b)$ : The open interval of $a$ and $b$ is the set of all real numbers that are within $a$ and $b$ : $(a, b) = \{x \in \mathbb{R} \mid a < x \leq b\}$ (11.2)

1.2. The Rational Numbers  $\mathbb{Q}$

<b>Example 11.1 Power Set/Cardinality of</b> $S = \{x, y, z\}$ : The subsets of S are: $\{\emptyset\}, \{x\}, \{y\}, \{z\}, \{x, y\}, \{x, z\}, \{y, z\}, \{x, y, z\}$ and hence the power set of $S$ is $\mathcal{P}(S) = \{\{\emptyset\}, \{x\}, \{y\}, \{z\}, \{x, y\}, \{x, z\}, \{y, z\}, \{x, y, z\}\}$ with a cardinality of $ S  = 2^3 = 8$ .
--

Sequences&Series

<b>Definition 12.1 Index Set</b> : Is a set <sup>[def. 11.1]</sup> $A$ , whose members are labels to another set $S$ . In other words its members index member of another set. An index set is build by enumerating the members of $S$ using a function $f$ s.t. $f : A \mapsto S \qquad A \in \mathbb{N}$ (12.1)
<b>Definition 12.2 Sequence</b> $(a_n)_{n \in A}$ : is an by an index set $A$ <i>enumerated</i> multiset <sup>[def. 11.3]</sup> (repetitions are allowed) of objects in which <i>order does matter</i> .
<b>Definition 12.3 Series</b> : is an infinite ordered set of terms combined together by addition.

1. Types of Sequences

1.1. Arithmetic Sequence

<b>Definition 12.4 Arithmetic Sequence</b> : Is a sequence where the <i>difference</i> between two consecutive terms constant i.e. $(2, 4, 6, 8, 10, 12, \dots)$ . $t_n = t_0 + nd \quad d$ :difference between two terms (12.2)
---

1.2. Geometric Sequence

<b>Definition 12.5 Geometric Sequence</b> : Is a sequence where the <i>ratio</i> between two consecutive terms constant i.e. $(2, 4, 8, 16, 32, \dots)$ . $t_n = t_0 \cdot r^n \qquad r$ :ratio between two terms (12.3)
---

# Calculus and Analysis

## 1. Building Blocks of Analysis

### 1.1. Polynomials

**Definition 13.1 Polynomial:** A function  $\mathcal{P}_n : \mathbb{R} \mapsto \mathbb{R}$  is called *Polynomial*, if it can be represented in the form:  
$$\mathcal{P}_n(x) = a_0 + a_1x + a_2x^2 + \cdots + a_{n-1}x^{n-1} + a_nx^n \quad (13.1)$$

**Corollary 13.1 Degree n-of a Polynomial**  $\deg(\mathcal{P}_n)$ : the *degree* of the polynomial is the highest exponent of the variable  $x$ , among all non-zero coefficients  $a_i \neq 0$ .

**Definition 13.2 Monomial:** Is a polynomial with only one term.

**Definition 13.3 Quadratic Formula:**  $ax^2 + bx + c = 0$  or in reduced form:  
 $x^2 + px + q = 0$  with  $p = b/a$  and  $q = c/a$

**Definition 13.4 Discriminant:**  $\delta = b^2 - 4ac$

**Definition 13.5 Solution to** <sup>[def. 13.3]</sup>:  
$$x_{\pm} = \frac{-b \pm \sqrt{\delta}}{2a} \quad \text{or} \quad x_{\pm} = \frac{1}{2} \left( -p \pm \sqrt{p^2 - 4q} \right)$$

**Theorem 13.1**  
**Fist Fundamental Theorem of Calculus:** Let  $f$  be a continuous real-valued function defined on a closed interval  $[a, b]$ . Let  $F$  be the function defined  $\forall x \in [a, b]$  by:

$$F(X) = \int_a^x f(t) dt \quad (13.2)$$

Then it follows:  
$$F'(x) = f(x) \quad \forall x \in (a, b) \quad (13.3)$$

**Theorem 13.2**  
**Second Fundamental Theorem of Calculus:** Let  $f$  be a real-valued function on a closed interval  $[a, b]$  and  $F$  an antiderivative of  $f$  in  $[a, b]$ :  $F'(x) = f(x)$ , then it follows if  $f$  is Riemann integrable on  $[a, b]$ :

$$\int_a^b f(t) dt = F(b) - F(a) \iff \int_a^x \frac{\partial}{\partial x} F(t) dt = F(x) \quad (13.4)$$

**Definition 13.6 Domain of a function**  $\text{dom}(\cdot)$ :  
**Given** a function  $f : \mathcal{X} \rightarrow \mathcal{Y}$ , the set of all possible input values  $\mathcal{X}$  is called the domain of  $f - \text{dom}(f)$ .

**Definition 13.7**  
**Codomain/target set of a function**  $\text{codom}(\cdot)$ :  
**Given** a function  $f : \mathcal{X} \rightarrow \mathcal{Y}$ , the codaomain of that function is the set  $\mathcal{Y}$  into which all of the output of the function is constrained to fall.

**Definition 13.8 Image (Range) of a function:**  $f[\cdot]$   
**Given** a function  $f : \mathcal{X} \rightarrow \mathcal{Y}$ , the image of that function is the set to which the function can actually map:  
$$\{y \in \mathcal{Y} | y = f(x), \quad \forall x \in \mathcal{X}\} := f[\mathcal{X}] \quad (13.5)$$

Evaluating the function  $f$  at each element of a given subset  $A$  of its domain  $\text{dom}(f)$  produces a set called the *image* of  $A$  under (or through)  $f$ . The image is thus a subset of a function's codomain.

**Definition 13.9 Inverse Image/Preimage**  $f^{-1}(\cdot)$ :  
Let  $f : X \mapsto Y$  be a function, and  $A$  a subset set of its codomain  $Y$ .  
Then the preimage of  $A$  under  $f$  is the set of all elements of the domain  $X$ , that map to elements in  $A$  under  $f$ :  
$$f^{-1}(A) = \{x \subseteq X : f(x) \subseteq A\} \quad (13.6)$$

**Example 13.1 :**  
**Given**  $f : \mathbb{R} \rightarrow \mathbb{R}$   
defined by  $f : x \mapsto x^2 \iff f(x) = x^2$   
 $\text{dom}(f) = \mathbb{R}$ ,  $\text{codom}(f) = \mathbb{R}$  but its image is  $f[\mathbb{R}] = \mathbb{R}_+$ .

#### Image (Range) of a subset

The image of a subset  $A \subseteq \mathcal{X}$  under  $f$  is the subset  $f[A] \subseteq \mathcal{Y}$  defined by:

$$f[A] = \{y \in \mathcal{Y} | y = f(x), \quad \forall x \in A\} \quad (13.7)$$

#### Note: Range

The term range is ambiguous as it may refer to the image or the codomain, depending on the definition. However, modern usage almost always uses range to mean image.

**Definition 13.10 (strictly) Increasing Functions:**  
A function  $f$  is called **monotonically increasing/ increasing/non-decreasing** if:  
$$x \leq y \iff f(x) \leq f(y) \quad \forall x, y \in \text{dom}(f) \quad (13.8)$$
  
And **strictly increasing** if:  
$$x < y \iff f(x) < f(y) \quad \forall x, y \in \text{dom}(f) \quad (13.9)$$

**Definition 13.11 (strictly) Decreasing Functions:**  
A function  $f$  is called monotonically decreasing/decreasing or non-increasing if:  
$$x \geq y \iff f(x) \geq f(y) \quad \forall x, y \in \text{dom}(f) \quad (13.10)$$
  
And **strictly decreasing** if:  
$$x > y \iff f(x) > f(y) \quad \forall x, y \in \text{dom}(f) \quad (13.11)$$

**Definition 13.12 Monotonic Function:** A function  $f$  is called monotonic iff either  $f$  is **increasing** or **decreasing**.

**Definition 13.13 Linear Function:**  
A function  $L : \mathbb{R}^n \mapsto \mathbb{R}^m$  is linear if and only if:  
$$L(\mathbf{x} + \mathbf{y}) = L(\mathbf{x}) + L(\mathbf{y})$$
$$L(\alpha \mathbf{x}) = \alpha L(\mathbf{x}) \quad \forall \mathbf{x}, \mathbf{y} \in \mathbb{R}^n, \quad \alpha \in \mathbb{R}$$

**Corollary 13.2 Linearity of Differentiation:** The derivative of **any** linear combination of functions equals the same linear combination of the derivatives of the functions:  
$$\frac{d}{dx} (af(x) + bg(x)) = a \frac{d}{dx} f(x) + b \frac{d}{dx} g(x) \quad a, b \in \mathbb{R} \quad (13.12)$$

**Definition 13.14 Quadratic Function:**  
A function  $f : \mathbb{R}^n \mapsto \mathbb{R}^m$  is quadratic if it can be written in the form:  
$$f(x) = \frac{1}{2} \mathbf{x}^T \mathbf{A} \mathbf{x} + \mathbf{b}^T \mathbf{x} + c \quad (13.13)$$

## 2. Continuity and Smoothness

**Definition 13.15 Continuous Function:**  
**Definition 13.16 Smoothness of a Function**  
**tcblackC<sup>k</sup>:** **Given** a function  $f : \mathcal{X} \rightarrow \mathcal{Y}$ , the function is said to be of class  $k$  if it is differentiable up to order  $k$  and continuous, on its entire domain:  
$$f \in C^k(\mathcal{X}) \iff \exists f', f'', \dots, f^{(k)} \text{ continuous} \quad (13.14)$$

#### Note

- The class  $C^0$  consists of all continuous functions.
- P.w. continuous  $\neq$  continuous.
- A function of that is  $k$  times differentiable must at least be of class  $C^{k-1}$ .
- $C^m(\mathcal{X}) \subset C^{m-1}, \dots, C^1 \subset C^0$
- Continuity is implied by the differentiability of all **derivatives** of up to order  $k - 1$ .

**Corollary 13.3 Smooth Function**  $C^\infty$ : Is a function  $f : \mathcal{X} \rightarrow \mathcal{Y}$  that has derivatives infinitely many times differentiable.  
$$f \in C^\infty(\mathcal{X}) \iff f', f'', \dots, f^{(\infty)} \quad (13.15)$$

**Corollary 13.4 Continuously Differentiable Function**  $C^1$ : Is the class of functions that consists of all differentiable functions whose derivative is continuous.  
Hence a function  $f : \mathcal{X} \rightarrow \mathcal{Y}$  of the class must satisfy:  
$$f \in C^1(\mathcal{X}) \iff f' \text{ continuous} \quad (13.16)$$

Often functions are not differentiable but we still want to state something about the rate of change of a function  $\Rightarrow$  hence we need a weaker notion of differentiability.

**Definition 13.17 Lipschitz Continuity:** A Lipschitz continuous function is a function  $f$  whose rate of change is bound by a Lipschitz Contant  $L$ :  
$$|f(x) - f(y)| \leq L \|x - y\|_2^2 \quad \forall \mathbf{x}, \mathbf{y}, \quad L > 0 \quad (13.17)$$

#### Note

This property is useful as it allows us to conclude that a small perturbation in the input (i.e. of an algorithm) will result in small changes of the output  $\Rightarrow$  tells us something about robustness.

**Definition 13.18 Lipschitz Continuous Gradient:**  
A *continuously differentiable* function  $f : \mathbb{R}^d \mapsto \mathbb{R}$  has *L-Lipschitz continuous gradient* if it satisfies:  
$$\|\nabla f(\mathbf{x}) - \nabla f(\mathbf{y})\| \leq L \|\mathbf{x} - \mathbf{y}\| \quad \forall \mathbf{x}, \mathbf{y} \in \text{dom}(f), \quad L > 0 \quad (13.18)$$

if  $f \in C^2$ , this is equivalent to:  
$$\nabla^2 f(\mathbf{x}) \leq L \mathbf{I} \quad \forall \mathbf{x} \in \text{dom}(f), \quad L > 0 \quad (13.19)$$

**Lemma 13.1 Descent Lemma:** If a function  $f : \mathbb{R}^d \mapsto \mathbb{R}$  has *Lipschitz continuous gradient* eq. (13.18) over its domain, then it holds that:

$$|f(\mathbf{x}) - f(\mathbf{y}) - \nabla f(\mathbf{y})^T (\mathbf{x} - \mathbf{y})| \leq \frac{L}{2} \|\mathbf{x} - \mathbf{y}\|^2 \quad (13.20)$$

#### Note

If  $f$  is twice differentiable then the largest eigenvalue of the Hessian <sup>(def. 14.5)</sup> of  $f$  is uniformly upper bounded by  $L$

*Proof.* lemma 13.1 for  $C^1$  functions:  
Let  $g(t) \equiv f(\mathbf{y} + t(\mathbf{x} - \mathbf{y}))$  from the FToC (theorem 13.2) we know that:

$$\int_0^1 g'(t) dt = g(1) - g(0) = f(\mathbf{x}) - f(\mathbf{y})$$

It then follows from the reverse:  
$$|f(\mathbf{x}) - f(\mathbf{y}) - \nabla f(\mathbf{y})^T (\mathbf{x} - \mathbf{y})|$$

$$\begin{aligned} & \stackrel{\text{Chain. R}}{\underset{\text{FTOC}}{=}} \left| \int_0^1 \nabla f(\mathbf{y} + t(\mathbf{x} - \mathbf{y}))^T (\mathbf{x} - \mathbf{y}) dt - \nabla f(\mathbf{y})^T (\mathbf{x} - \mathbf{y}) \right| \\ &= \left| \int_0^1 (\nabla f(\mathbf{y} + t(\mathbf{x} - \mathbf{y})) - \nabla f(\mathbf{y}))^T (\mathbf{x} - \mathbf{y}) dt \right| \\ &= \left| \int_0^1 (\nabla f(\mathbf{y} + t(\mathbf{x} - \mathbf{y})) - \nabla f(\mathbf{y}))^T (\mathbf{x} - \mathbf{y}) dt \right| \\ & \stackrel{\text{C.S.}}{\leq} \left| \int_0^1 \|\nabla f(\mathbf{y} + t(\mathbf{x} - \mathbf{y})) - \nabla f(\mathbf{y})\| \cdot \|\mathbf{x} - \mathbf{y}\| dt \right| \\ & \stackrel{\text{eq. (13.18)}}{=} \left| \int_0^1 L \|\mathbf{y} + t(\mathbf{x} - \mathbf{y}) - \mathbf{y}\| \cdot \|\mathbf{x} - \mathbf{y}\| dt \right| \\ &= \left| L \|\mathbf{x} - \mathbf{y}\|^2 \int_0^1 t dt \right| = \frac{L}{2} \|\mathbf{x} - \mathbf{y}\|^2 \end{aligned}$$

*Proof.* lemma 13.1 for  $C^2$  functions:

$$f(\mathbf{y}) \stackrel{\text{Taylor}}{=} f(\mathbf{x}) + \nabla f(\mathbf{x})^T (\mathbf{y} - \mathbf{x}) + \frac{1}{2} (\mathbf{y} - \mathbf{x})^T \nabla^2 f(z) (\mathbf{y} - \mathbf{x})$$

Now we plug in  $\nabla^2 f(\mathbf{x})$  and recover eq. (13.21):

$$f(\mathbf{y}) \leq f(\mathbf{x}) + \nabla f(\mathbf{x})^T (\mathbf{y} - \mathbf{x}) + \frac{1}{2} (\mathbf{y} - \mathbf{x})^T L (\mathbf{y} - \mathbf{x})$$

□

**Definition 13.19 L-Smoothness:** A  $L$ -smooth function is a function  $f : \mathbb{R}^d \mapsto \mathbb{R}$  that satisfies:

$$f(\mathbf{x}) \leq f(\mathbf{y}) + \nabla f(\mathbf{y})^T (\mathbf{x} - \mathbf{y}) + \frac{L}{2} \|\mathbf{x} - \mathbf{y}\|^2$$

with  $\forall \mathbf{x}, \mathbf{y} \in \text{dom}(f), \quad L > 0 \quad (13.21)$

If  $f$  is a twice differentiable this is equivalent to:  
$$\nabla^2 f(\mathbf{x}) \leq L \mathbf{I} \quad L > 0 \quad (13.22)$$

**Theorem 13.3**  
**L-Smoothness of convex functions:**  
A *convex* and L-Smooth function <sup>(def. 13.19)</sup> has a Lipschitz continuous gradient (eq. (13.18)) thus it holds that:  
$$f(\mathbf{x}) \leq f(\mathbf{y}) + \nabla f(\mathbf{y})^T (\mathbf{x} - \mathbf{y}) \leq \frac{L}{2} \|\mathbf{x} - \mathbf{y}\|^2 \quad (13.23)$$

*Proof.* theorem 13.3:  
With the definition of convexity for a differentiable function (eq. (13.26)) it follows  
$$f(\mathbf{x}) - f(\mathbf{y}) + \nabla f(\mathbf{y})^T (\mathbf{x} - \mathbf{y}) \geq 0$$
$$\Rightarrow |f(\mathbf{x}) - f(\mathbf{y}) + \nabla f(\mathbf{y})^T (\mathbf{x} - \mathbf{y})|$$
  
if eq. <sup>(13.26)</sup>  $f(\mathbf{x}) - f(\mathbf{y}) + \nabla f(\mathbf{y})^T (\mathbf{x} - \mathbf{y})$

with lemma 13.1 and <sup>[def. 13.19]</sup> it follows theorem 13.3 □

**Corollary 13.5 :**  $L$ -smoothnes is a weaker condition than  $L$ -Lipschitz continuous gradients

## 3. Convexity

Read stuff about uniqueness and so on again in NPDE/or NUM CSE and add proofs

**Definition 13.20 Convex Functions:**  
A function  $f : \mathbb{R}^n \mapsto \mathbb{R}$  is convex if it satisfies:  
$$f(\lambda \mathbf{x} + (1 - \lambda) \mathbf{y}) \leq \lambda f(\mathbf{x}) + (1 - \lambda) f(\mathbf{y}) \quad \forall \mathbf{x}, \mathbf{y} \in \text{dom}(f) \quad \forall \lambda \in [0, 1] \quad (13.24)$$

include figure from tika/convexity

**Definition 13.21 Concave Functions:**  
A function  $f : \mathbb{R}^n \mapsto \mathbb{R}$  is concave if it satisfies:  
$$f(\lambda \mathbf{x} + (1 - \lambda) \mathbf{y}) \geq \lambda f(\mathbf{x}) + (1 - \lambda) f(\mathbf{y}) \quad \forall \mathbf{x}, \mathbf{y} \in \text{dom}(f) \quad \forall \lambda \in [0, 1] \quad (13.25)$$

**Corollary 13.6 Convexity  $\rightarrow$  global minimima:** Convexity implies that all local minima (if they exist) are global minima.

**Definition 13.22 Stricly Convex Functions:**  
A function  $f : \mathbb{R}^n \mapsto \mathbb{R}$  is **strictly** convex if it satisfies:  
$$f(\lambda \mathbf{x} + (1 - \lambda) \mathbf{y}) < \lambda f(\mathbf{x}) + (1 - \lambda) f(\mathbf{y}) \quad \forall \mathbf{x}, \mathbf{y} \in \text{dom}(f) \quad \forall \lambda \in [0, 1]$$

add plot

If  $f$  is a differentiable function this is equivalent to:  
$$f(\mathbf{x}) \geq f(\mathbf{y}) + \nabla f(\mathbf{y})^T (\mathbf{x} - \mathbf{y}) \quad \forall \mathbf{x}, \mathbf{y} \in \text{dom}(f) \quad (13.26)$$

If  $f$  is a twice differentiable function this is equivalent to:  
$$\nabla^2 f(\mathbf{x}) \geq 0 \quad \forall \mathbf{x}, \mathbf{y} \in \text{dom}(f) \quad (13.27)$$

#### Intuition

- Convexity implies that a function  $f$  is bound by/below a linear interpolation from  $x$  to  $y$  and strong convexity that  $f$  is strictly bound/below.
- eq. (13.26) implies that  $f(\mathbf{x})$  is above the tangent  $f(\mathbf{x}) + \nabla f(\mathbf{x})^T (\mathbf{y} - \mathbf{x})$  for all  $\mathbf{x}, \mathbf{y} \in \text{dom}(f)$
- ?? implies that  $f(\mathbf{x})$  is flat or curved upwards

**Corollary 13.7 Strict Convexity  $\rightarrow$  Uniqueness:**  
Strict convexity implies a unique minimizer  $\iff$  at most one global minimum.

**Corollary 13.8 :** A twice differentiable function of one variable  $f : \mathbb{R} \rightarrow \mathbb{R}$  is **convex** on an interval  $\mathcal{X} = [a, b]$  if and only if its second derivative is non-negative on that interval  $\mathcal{X}$ :

$$f''(x) \geq 0 \quad \forall x \in \mathcal{X} \quad (13.28)$$

**Definition 13.23  $\mu$ -Strong Convexity:**  
Let  $\mathcal{X}$  be a Banach space over  $\mathbb{K} = \mathbb{R}, \mathbb{C}$ . A function  $f : \mathcal{X} \rightarrow \mathbb{R}$  is called strongly convex iff the following equation holds:

$$f(tx + (1-t)y) \leq tf(x) + (1-t)f(y) - \frac{t(1-t)}{2} \mu \|x - y\| \quad \forall x, y \in \mathcal{X}, \quad t \in [0, 1], \quad \mu > 0$$

If  $f \in \mathcal{C}^1 \iff f$  is differentiable, this is equivalent to:

$$f(y) \geq f(x) + \nabla f(x)^\top (y - x) + \frac{\mu}{2} \|y - x\|_2^2 \quad (13.29)$$

If  $f \in \mathcal{C}^2 \iff f$  is twice differentiable, this is equivalent to:

$$\nabla^2 f(x) \geq \mu \mathbf{I} \quad \forall x, y \in \mathcal{X} \quad \mu > 0 \quad (13.30)$$

**Corollary 13.9 Strong Convexity implies Strict Convexity:**  
<https://math.stackexchange.com/question/2090991/proofofstrongly-convex-function-is-strictly-convex>

**Property 13.1:**

$$f(y) \leq f(y) + \nabla f(y)^\top (x - y) + \frac{1}{2\mu} \|\nabla f(x) - \nabla f(y)\|_2^2 \quad (13.31)$$

**Intuition**  
Strong convexity implies that a function  $f$  is lower bounded by its second order (quadratic) approximation, rather than only its first order (linear) approximation.

**Size of  $\mu$**   
The parameter  $\mu$  specifies how strongly the bounding quadratic function/approximation is.

*Proof.* eq. (13.30) analogously to **Proof** eq. (13.22)  $\square$

**Note**  
If  $f$  is twice differentiable then the smallest eigenvalue of the Hessian (<sup>[def. 14.5]</sup>) of  $f$  is uniformly lower bounded by  $\mu$ .  
**Hence** strong convexity can be considered as the analogous to smoothness

**Example 13.2 Quadratic Function:** A quadratic function eq. (13.13) is convex if:

$$\nabla_{\mathbf{x}}^2 \text{eq. (13.13)} = \mathbf{A} \geq 0 \quad (13.32)$$

**Corollary 13.10 :**  
Strong convexity  $\Rightarrow$  Strict convexity  $\Rightarrow$  Convexity

**3.1. Properties that preserve convexity**

**Property 13.2 Non-negative weighted Sums:** Let  $f$  be a convex function then  $g(x)$  is convex as well:

$$g(x) = \sum_{i=1}^n \alpha_i f_i(x) \quad \forall \alpha_j > 0$$

**Property 13.3 Composition of Affine Mappings:** Let  $f$  be a convex function then  $g(x)$  is convex as well:

$$g(x) = f(\mathbf{Ax} + \mathbf{b})$$

**Property 13.4 Pointwise Maxima:** Let  $f$  be a convex function then  $g(x)$  is convex as well:

$$g(x) = \max_i \{f_i(x)\}$$

**Functions**

**Even Functions:** have rotational symmetry with respect to the origin.  
 $\Rightarrow$  **Geometrically:** its graph remains unchanged after reflection about the y-axis.

$$f(-x) = f(x) \quad (13.33)$$

**Odd Functions:** are symmetric w.r.t. to the y-axis.  
 $\Rightarrow$  **Geometrically:** its graph remains unchanged after rotation of 180 degrees about the origin.

$$f(-x) = -f(x) \quad (13.34)$$

**Theorem 13.4 Rules:**  
**Let  $f$  be even and  $f$  odd respectively.**  
 $g =: f \cdot f$  is even  $g =: f \cdot f$  is even  
 $g =: f \cdot f$  is odd the same holds for division

**Examples**

**Even:**  $\cos x, |x|, \mathbf{c}, x^2, x^4, \dots \exp(-x^2/2)$ .  
**Odd:**  $\sin x, \tan x, x, x^3, x^5, \dots$

**x-Shift:**  $f(x - \mathbf{c}) \Rightarrow$  shift to the right  
 $f(x + \mathbf{c}) \Rightarrow$  shift to the left  
**y-Shift:**  $f(x) \pm \mathbf{c} \Rightarrow$  shift up/down

*Proof.* eq. (13.35)  $f(x_n - \mathbf{c})$  we take the  $x$ -value at  $x_n$  but take the  $y$ -value at  $x_o := x_n - \mathbf{c} \Rightarrow$  we shift the function to  $x_n$ .  $\square$

**Euler's formula**

$$e^{\pm ix} = \cos x \pm i \sin x \quad (13.37)$$

**Euler's Identity**

$$e^{\pm i} = -1 \quad (13.38)$$

**Note**

$$e^n = 1 \iff n = i2\pi k, \quad k \in \mathbb{N} \quad (13.39)$$

**Corollary 13.11 Every norm is a convex function:** By using definition (<sup>[def. 13.20]</sup>) and the triangular inequality it follows (with the exception of the L0-norm):

$$\|\lambda x + (1 - \lambda)y\| \leq \lambda \|x\| + (1 - \lambda) \|y\|$$

**3.2. Taylor Expansion**

**Definition 13.24 Taylor Expansion:**

$$T_n(x) = \sum_{i=0}^n \frac{1}{i!} f^{(i)}(x_0) \cdot (x - x_0)^{(i)} \quad (13.40)$$
$$= f(x_0) + f'(x_0)(x - x_0) + \frac{1}{2} f''(x_0)(x - x_0)^2 + \mathcal{O}(x^3) \quad (13.41)$$

**Definition 13.25 Incremental Taylor:**  
**Goal:** evaluate  $T_n(x)$  (eq. (13.41)) at the point  $x_0 + \Delta x$  in order to propagate the function  $f(x)$  by  $h = \Delta x$ :

$$T_n(x_0 \pm h) = \sum_{i=0}^n \frac{h^i}{i!} f^{(i)}(x_0) i^{-1} \quad (13.42)$$
$$= f(x_0) \pm h f'(x_0) + \frac{h^2}{2} f''(x_0) \pm f'''(x_0)(h)^3 + \mathcal{O}(h^4)$$

**Note**  
If we chose  $\Delta x$  small enough it is sufficient to look only at the first two terms.

**Definition 13.26 Multidimensional Taylor:** Suppose  $X \in \mathbb{R}^n$  is open,  $\mathbf{x} \in X, f : X \mapsto \mathbb{R}$  and  $f \in \mathcal{C}^2$  then it holds that

$$f(\mathbf{x}) \approx f(\mathbf{x}_0) + \nabla_{\mathbf{x}} f(\mathbf{x}_0)(\mathbf{x} - \mathbf{x}_0) + \frac{1}{2} (\mathbf{x} - \mathbf{x}_0)^\top H(\mathbf{x} - \mathbf{x}_0) \quad (13.43)$$

**Definition 13.27 Argmax:** The argmax of a function defined on a set  $D$  is given by:

$$\arg \max_{x \in D} f(x) = \{x | f(x) \geq f(y), \forall y \in D\} \quad (13.44)$$

**Definition 13.28 Argmin:** The argmin of a function defined on a set  $D$  is given by:

$$\arg \min_{x \in D} f(x) = \{x | f(x) \leq f(y), \forall y \in D\} \quad (13.45)$$

**Corollary 13.12 Relationship**  $\arg \min \leftrightarrow \arg \max$ :

$$\arg \min_{x \in D} f(x) = \arg \max_{x \in D} -f(x) \quad (13.46)$$

**Property 13.5 Argmax Identities:**

- Shifting:**  $\forall \lambda \text{ const} \quad \arg \max f(x) = \arg \max f(x) + \lambda \quad (13.47)$
- Positive Scaling:**  $\forall \lambda > 0 \text{ const} \quad \arg \max f(x) = \arg \max \lambda f(x) \quad (13.48)$
- Negative Scaling:**  $\forall \lambda < 0 \text{ const} \quad \arg \max f(x) = \arg \min \lambda f(x) \quad (13.49)$
- Positive Functions:**  $\forall \arg \max f(x) > 0, \forall x \in \text{dom}(f)$   
 $\arg \max f(x) = \arg \min \frac{1}{f(x)} \quad (13.50)$
- Stricly Monotonic Functions:** for all strictly monotonic increasing functions (<sup>[def. 13.10]</sup>)  $g$  it holds that:  
 $\arg \max g(f(x)) = \arg \max f(x) \quad (13.51)$

**Definition 13.29 Max:** The maximum of a function  $f$  defined on the set  $D$  is given by:

$$\max_{x \in D} f(x) = f(x^*) \quad \text{with} \quad \forall x^* \in \arg \max f(x) \quad (13.52)$$

**Definition 13.30 Min:** The minimum of a function  $f$  defined on the set  $D$  is given by:

$$\min_{x \in D} f(x) = f(x^*) \quad \text{with} \quad \forall x^* \in \arg \min f(x) \quad (13.53)$$

**Corollary 13.13 Relationship**  $\min \leftrightarrow \max$ :

$$\min_{x \in D} f(x) = - \max_{x \in D} -f(x) \quad (13.54)$$

**Property 13.6 Max Identities:**

- Shifting:**  $\forall \lambda \text{ const} \quad \max \{f(x) + \lambda\} = \lambda + \max f(x) \quad (13.55)$
- Positive Scaling:**  $\forall \lambda > 0 \text{ const} \quad \max \lambda f(x) = \lambda \max f(x) \quad (13.56)$
- Negative Scaling:**  $\forall \lambda < 0 \text{ const} \quad \max \lambda f(x) = \lambda \min f(x) \quad (13.57)$
- Positive Functions:**  $\forall \arg \max f(x) > 0, \forall x \in \text{dom}(f) \quad \max \frac{1}{f(x)} = \frac{1}{\min f(x)} \quad (13.58)$
- Stricly Monotonic Functions:** for all strictly monotonic increasing functions (<sup>[def. 13.10]</sup>)  $g$  it holds that:  
 $\max g(f(x)) = g(\max f(x)) \quad (13.59)$

**Definition 13.31 Supremum:** The supremum of a function defined on a set  $D$  is given by:

$$\sup_{x \in D} f(x) = \{y | y \geq f(x), \forall x \in D\} = \min_{y | y \geq f(x), \forall x \in D} y \quad (13.60)$$

and is the smallest value  $y$  that is equal or greater  $f(x)$  for any  $x \iff$  smallest upper bound.

**Definition 13.32 Infimum:** The infimum of a function defined on a set  $D$  is given by:

$$\inf_{x \in D} f(x) = \{y | y \leq f(x), \forall x \in D\} = \max_{y | y \leq f(x), \forall x \in D} y \quad (13.61)$$

and is the biggest value  $y$  that is equal or smaller  $f(x)$  for any  $x \iff$  largest lower bound.

**Corollary 13.14 Relationship**  $\sup \leftrightarrow \inf$ :

$$\inf_{x \in D} f(x) = - \sup_{x \in D} -f(x) \quad (13.62)$$

**Note**  
The supremum/infimum is necessary to handle unbound function that seem to converge and for which the max/min does not exist as the argmax/argmin may be empty.  
E.g. consider  $-e^x/e^x$  for which the max/min converges toward 0 but will never reached s.t. we can always choose a bigger  $x \Rightarrow$  there exists no argmax/argmin  $\Rightarrow$  need to bound the functions from above/below  $\iff$  infimum/supremum.

**Definition 13.33 Time-invariant system (TIS):** A function  $f$  is called time-invariant, if shifting the input in time leads to the same output shifted in time by the same amount.

$$y(t) = f(x(t), t) \xrightarrow{\text{time-invariance}} y(t - \tau) = f(x(t - \tau), t) \quad \forall \tau \quad (13.63)$$

**Definition 13.34 Inverse Function**  $g = f^{-1}$ :  
A function  $g$  is the inverse function of the function  $f : A \subset \mathbb{R} \rightarrow B \subset \mathbb{R}$  if

$$f(g(x)) = x \quad \forall x \in \text{dom}(g) \quad (13.64)$$

and

$$g(f(u)) = u \quad \forall u \in \text{dom}(f) \quad (13.65)$$

**Property 13.7**  
**Reflective Property of Inverse Functions:**  $f$  contains  $(a, b)$  if and only if  $f^{-1}$  contains  $(b, a)$ .  
The line  $y = x$  is a symmetry line for  $f$  and  $f^{-1}$ .

**Theorem 13.5 The Existence of an Inverse Function:**  
A function has an inverse function if and only if it is one-to-one.

**Corollary 13.15 Inverse functions and strict monotonicity:** If a function  $f$  is **strictly monotonic** (<sup>[def. 13.12]</sup>) on its entire domain, then it is one-to-one and therefore has an inverse function.

**4. Special Functions**

**4.1. The Gamma Function**

**Definition 13.35 The gamma function  $\Gamma(\alpha)$ :** Is extension of the factorial function (??) to the real and complex numbers (with a positive real part):

$$\Gamma(z) = \int_0^\infty x^{z-1} e^{-x} dx \quad \Re(z) > 0 \quad (13.66)$$
$$\Gamma(n) \xleftrightarrow{n \in \mathbb{N}} \Gamma(n) = (n-1)!$$

Differential Calculus

**Definition 14.1 Critical/Stationary Point:** Given a function  $f : \mathbb{R}^n \mapsto \mathbb{R}$ , that is differentiable at a point  $\mathbf{x}_0$  then it is called a **critical point** if the functions derivative vanishes at that point:

$$f'(\mathbf{x}_0) = 0 \iff \nabla_{\mathbf{x}} f(\mathbf{x}_0) = 0$$

**Definition 14.2 Second Derivative**  $\frac{\partial^2}{\partial x_i \partial x_j}$ :

**Corollary 14.1 Second Derivative Test**  $f : \mathbb{R} \mapsto \mathbb{R}$ : Suppose  $f : \mathbb{R} \mapsto \mathbb{R}$  is twice differentiable at a stationary point  $x$  <sup>[def. 14.1]</sup> then it follows that:

- $f''(x) > 0 \iff \begin{matrix} f'(x + \epsilon) > 0 & \text{slope points uphill} \\ f'(x - \epsilon) < 0 & \text{slope points downhill} \\ f(x) \text{ is a local minimum} \end{matrix}$
- $f''(x) < 0 \iff \begin{matrix} f'(x + \epsilon) > 0 & \text{slope points downhill} \\ f'(x - \epsilon) < 0 & \text{slope points uphill} \\ f(x) \text{ is a local maximum} \end{matrix}$

$\epsilon > 0$  sufficiently small enough

**Definition 14.3 Gradient:** Given  $f : n \mapsto \mathbb{R}$  its gradient is defined as:

$$\text{grad}_{\mathbf{x}}(f) = \nabla_{\mathbf{x}} f := \begin{bmatrix} \frac{\partial f}{\partial x_1} & \frac{\partial f}{\partial x_2} & \cdots & \frac{\partial f}{\partial x_n} \end{bmatrix} \quad (14.1)$$

**Definition 14.4 Jacobi Matrix:** Given a vector valued function  $f : \mathbb{R}^n \mapsto \mathbb{R}^m$  its derivative/Jacobian is defined as:

$$\mathbf{J}(f(\mathbf{x})) = \mathbf{J}_f(\mathbf{x}) = \mathbf{D}f = \frac{\partial \mathbf{f}}{\partial \mathbf{x}}(\mathbf{x}) = \frac{\partial (f_1, \dots, f_m)}{\partial (x_1, \dots, x_n)}(\mathbf{x}) = \quad (14.2)$$

$$= \begin{bmatrix} \frac{\partial f_1}{\partial x_1}(\mathbf{x}) & \frac{\partial f_1}{\partial x_2}(\mathbf{x}) & \cdots & \frac{\partial f_1}{\partial x_n}(\mathbf{x}) \\ \frac{\partial f_2}{\partial x_1}(\mathbf{x}) & \frac{\partial f_2}{\partial x_2}(\mathbf{x}) & \cdots & \frac{\partial f_2}{\partial x_n}(\mathbf{x}) \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial f_m}{\partial x_1}(\mathbf{x}) & \frac{\partial f_m}{\partial x_2}(\mathbf{x}) & \cdots & \frac{\partial f_m}{\partial x_n}(\mathbf{x}) \end{bmatrix}$$

**Theorem 14.1 Symmetry of second derivatives/Schwartz's Theorem:** Given a continuous and twice differentiable function  $f : \mathbb{R}^n \mapsto \mathbb{R}$  then its second order partial derivatives commute:

$$\frac{\partial}{\partial x_i} \frac{\partial f}{\partial x_j} = \frac{\partial}{\partial x_j} \frac{\partial f}{\partial x_i}$$

**Definition 14.5 Hessian Matrix:** Given a function  $f : \mathbb{R} \mapsto \mathbb{R}^n$  its Hessian  $\in \mathbb{R}^{n \times n}$  is defined as:

$$\mathbf{H}(f)(\mathbf{x}) = \mathbf{H}_f(\mathbf{x}) = \mathbf{J}(\nabla f(\mathbf{x}))^T \quad (14.3)$$

$$= \begin{bmatrix} \frac{\partial^2 f}{\partial x_1^2}(\mathbf{x}) & \frac{\partial^2 f}{\partial x_1 \partial x_2}(\mathbf{x}) & \cdots & \frac{\partial^2 f}{\partial x_1 \partial x_n}(\mathbf{x}) \\ \frac{\partial^2 f}{\partial x_2 \partial x_1}(\mathbf{x}) & \frac{\partial^2 f}{\partial x_2^2}(\mathbf{x}) & \cdots & \frac{\partial^2 f}{\partial x_2 \partial x_n}(\mathbf{x}) \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial^2 f}{\partial x_n \partial x_1}(\mathbf{x}) & \frac{\partial^2 f}{\partial x_n \partial x_2}(\mathbf{x}) & \cdots & \frac{\partial^2 f}{\partial x_n^2}(\mathbf{x}) \end{bmatrix}$$

and it corresponds to the Jacobian of the Gradient. Due to the differentiability and theorem 14.1 it follows that the Hessian is (if it exists):

- Symmetric
- Real

**Corollary 14.2 Eigenvector basis of the Hessian:** Due to the fact that the Hessian is real and symmetric we can decompose it into a set of real eigenvalues and an orthogonal basis of eigenvectors  $\{(\lambda_1, \mathbf{v}_1), \dots, (\lambda_n, \mathbf{v}_n)\}$ . Not let  $\mathbf{d}$  be a directional unit vector then the second derivative in that direction is given by:

$$\mathbf{d}^T \mathbf{H} \mathbf{d} \iff \mathbf{d}^T \sum_{i=1}^n \lambda_i \mathbf{v}_i \iff \text{if } \mathbf{d} = \mathbf{v}_j \iff \mathbf{d}^T \lambda_j \mathbf{v}_j$$

- The eigenvectors that have smaller angle with  $\mathbf{d}$  have bigger weight/eigenvalues
- The minimum/maximum eigenvalue determines the minimum/maximum second derivative

**Corollary 14.3 Second Derivative Test**  $f : \mathbb{R}^n \mapsto \mathbb{R}$ : Suppose  $f : \mathbb{R}^n \mapsto \mathbb{R}$  is twice differentiable at a stationary point  $\mathbf{x}$  <sup>[def. 14.1]</sup> then it follows that:

- If  $\mathbf{H}$  is **p.d**  $\iff \forall \lambda_i > 0 \in \mathbf{H} \rightarrow f(\mathbf{x})$  is a local min.
- If  $\mathbf{H}$  is **n.d**  $\iff \forall \lambda_i < 0 \in \mathbf{H} \rightarrow f(\mathbf{x})$  is a local max.
- If  $\exists \lambda_i > 0 \in \mathbf{H}$  and  $\exists \lambda_i < 0 \in \mathbf{H}$  then  $\mathbf{x}$  is a local maximum in one cross section of  $f$  but a local minimum in another
- If  $\exists \lambda_i = 0 \in \mathbf{H}$  and all other eigenvalues have the same sign the test is inclusive as it is inconclusive in the cross section corresponding to the zero eigenvalue.

Note

If  $\mathbf{H}$  is positive definite for a minima  $\mathbf{x}^*$  of a *quadratic* function  $f$  then this point must be a global minimum of that function.

Integral Calculus

Theorem 15.1 Important Integral Properties:

**Addition**  $\int\limits_a^b f(x) \, dx = \int\limits_a^c f(x) \, dx + \int\limits_c^b f(x) \, dx$  (15.1)

**Reflection**  $\int\limits_a^b f(x) \, dx = - \int\limits_b^a f(x) \, dx$  (15.2)

**Translation**  $\int\limits_a^b f(x) \, dx \stackrel{u:=x\pm c}{=} \int\limits_{a\pm c}^{b\pm c} f(x \mp c) \, dx$  (15.3)

$f$  **Odd**  $\int\limits_{-a}^a f(x) \, dx = 0$  (15.4)

$f$  **Even**  $\int\limits_{-a}^a f(x) \, dx = 2 \int\limits_0^a f(x) \, dx$  (15.5)

Proof. eqs. (15.4) and (15.5)

$$\begin{aligned} I &:= \int\limits_{-a}^a f(x) \, dx = \int\limits_{-a}^0 f(x) \, dx + \int\limits_0^a f(x) \, dx \\ &\stackrel{t=-x}{dt=-dx} = \int\limits_a^0 f(-x) \, dx + \int\limits_0^a f(x) \, dx \\ &= \int\limits_0^a f(-x) + f(x) \, dx = \begin{cases} 0 & \text{if } f \text{ odd} \\ 2I & \text{if } f \text{ even} \end{cases} \end{aligned}$$

□

Linear Algebra

Given a matrix  $A \in \mathbb{K}^{m,n}$

**Rank:**  $\text{rank}(A) = \dim(\mathfrak{R}(A))$   
of a matrix is the dimension of the vector space generated (or spanned) by its columns/rows.

**Span/Linear Hull:**  $\text{span}(v_1, v_2, \dots, v_n) = \{ \lambda_1 v_1, \lambda_2 v_2, \dots, \lambda_n v_n \} = \{ v \mid v = \sum_{i=1}^n \lambda_i v_i, \lambda_i \in \mathbb{R} \}$

Is the set of vectors tha can be expressed as a linear combination of the vectors  $v_1, \dots, v_n$ .

**Note** these vectors may be linearly independent.

**Generatring Set:** Is the set of vectors which span the  $\mathbb{R}^n$  that is:  $\text{span}(v_1, \dots, v_m) = \mathbb{R}^n$ .  
e.g.  $(4, 0)^T, (0, 5)^T$  span the  $\mathbb{R}^n$ .

**Basis  $\mathfrak{B}$ :** A lin. indep. generating set of the  $\mathbb{R}^n$  is called basis of the  $\mathbb{R}^n$ .

The unit vectors  $e_1, \dots, e_n$  build a standard basis of the  $\mathbb{R}^n$

**Vector Space**

**Image/Range:**  $\mathfrak{R}(A) := \{Ax \mid x \in \mathbb{K}^n\} \subset \mathbb{K}^n$

**Null-Space/Kernel:**  $\mathfrak{N} := \{z \in \mathbb{K}^n \mid Az = 0\}$

**Dimension theorem:**

**Theorem 16.1 Rank-Nullity theorem:** For any  $A \in \mathbb{Q}^{m \times n}$   
 $n = \dim(\mathfrak{N}[A]) + \dim(\mathfrak{R}[A])$

From orthogonality it follows  $x \in \mathfrak{R}(A), y \in \mathfrak{N}(A) \Rightarrow x^\top y = 0$ .

1. Transformations

1.1. Affine Transformations

**Definition 16.1 Affine Transfromation/Map:**  
Let  $x \in \mathbb{R}^n, A \in \mathbb{R}^{m \times n}, b \in \mathbb{R}^m$  then:  
 $Y = Ax + b$

is called an affine transformation of  $x$ .

2. Eigenvalues and Vectors

**Formula 16.1 Eigenvalues of a 2x2 matrix:** Given a 2x2-matrix  $A$  its eigenvalues can be calculated by:

$$\{\lambda_1, \lambda_2\} = \frac{\text{tr}(A) \pm \sqrt{\text{tr}(A)^2 - 4 \det(A)}}{2}$$

with  $\text{tr}(A) = a + d \quad \det(A) = ad - bc$

3. Special Kind of Vectors

**Definition 16.2 Orthogonal Vectors:** Let  $\mathcal{V}$  be an inner-product space<sup>[def. 16.19]</sup>. A set of vectors  $\{u_1, \dots, u_n, \dots\} \in \mathcal{V}$  is called *orthogonal* iff:  
 $\langle u_i, u_j \rangle = 0 \quad \forall i \neq j$

**Definition 16.3 Orthonormal Vectors:** Let  $\mathcal{V}$  be an inner-product space<sup>[def. 16.19]</sup>. A set of vectors  $\{u_1, \dots, u_n, \dots\} \in \mathcal{V}$  is called *orthonormal* iff:  
 $\langle u_i, u_j \rangle = \delta_{ij} = \begin{cases} 1 & i = j \\ 0 & i \neq j \end{cases} \quad \forall i, j$

4. Special Kind of Matrices

**Definition 16.4 Orthogonal Matrix:** A real valued square matrix  $Q \in \mathbb{R}^{n \times n}$  is said to be orthogonal if its row vectors (and respectively its column vectors) build an orthonormal basis:  
 $\langle q_i, q_j \rangle = \delta_{ij} \quad \text{and} \quad \langle q_i, q_j \rangle = \delta_{ij}$

This is exactly true if the inverse of  $Q$  equals its transpose:  
 $Q^{-1} = Q^\top \iff QQ^\top = Q^\top Q = I$

**Definition 16.5 Unitary/Hermitian Matrices:**  
 $A = A^H$

5. Block Partitioned Matrices

**Definition 16.6 Block Partitioned Matrix:**  
A matrix  $M \in \mathbb{R}^{k+l, k+l}$  can be partitioned into a *block partitioned matrix*:  
 $M = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \quad A \in \mathbb{R}^{k,k}, B \in \mathbb{R}^{k,l}, C \in \mathbb{R}^{l,k}, D \in \mathbb{R}^{l,l}$

**Definition 16.7 Block Partitioned Linear System:**  
A linear system  $Mx = b$  with  $M \in \mathbb{R}^{k+l, k+l}$  and  $x, b \in \mathbb{R}^{k+l}$  can be partitioned into a *block partitioned system*:  
 $\begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} b_1 \\ b_2 \end{bmatrix} \quad A \in \mathbb{R}^{k,k}, B \in \mathbb{R}^{k,l}, C \in \mathbb{R}^{l,k}, D \in \mathbb{R}^{l,l}$   
 $x_1, b_1 \in \mathbb{R}^k, x_2, b_2 \in \mathbb{R}^l$

5.1. Schur Complement

**Definition 16.8 Schur Complement:** Given a block partitioned matrix<sup>[def. 16.6]</sup>  $M \in \mathbb{R}^{k+l, k+l}$  its Schur complements are given by:  
 $S_A = D - CA^{-1}B \quad S_D = A - BD^{-1}C$

5.2. Inverse of Block Partitioned Matrix

**Definition 16.9 Inverse of a Block Partitioned Matrix:** proof 12  
Given a block partitioned matrix<sup>[def. 16.6]</sup>  $M \in \mathbb{R}^{k+l, k+l}$  its inverse  $M^{-1}$  can be partitioned as well:  
 $M = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \quad M^{-1} = \begin{bmatrix} \tilde{A} & \tilde{B} \\ \tilde{C} & \tilde{D} \end{bmatrix}$   
 $\tilde{A} = A^{-1} + A^{-1}BS^{-1}CA^{-1} \quad \tilde{C} = -S^{-1}CA^{-1}$   
 $\tilde{B} = -A^{-1}BS^{-1}A \quad \tilde{D} = S^{-1}A$   
where  $S_A = D - CA^{-1}B$  is the Schur complement of  $A$ .

5.3. Properties of Matrices

5.3.1. Square Root of p.s.d. Matrices

**Definition 16.10 Square Root:**

6. Matrix Operations

6.1. Trace

**Definition 16.11 Trace:** The trace of an  $A \in \mathbb{R}^{n \times n}$  matrix is defined as:  
 $\text{tr}(A) = \sum_{i=1}^n a_{ii} = a_{11} + a_{22} + \dots + a_{nn}$

**Property 16.1:**  
 $\text{tr}(\mathbb{R}) = \mathbb{R}$

**Property 16.2:**  
 $\text{tr}(A^\top) = \text{tr}(A)$

**Property 16.3:**  
 $\text{tr}(ABC) = \text{tr}(BCA) = \text{tr}(CBA)$

7. Decompositions

7.0.1. Eigendecomposition

**Definition 16.12 Eigendecomposition**  $A = Q\Lambda Q^{-1}$ :

7.0.2. Cholesky Decomposition

8. Spaces and Measures

**Definition 16.13 Bilinear Form/Functional:**  
Is a mapping  $a : \mathcal{V} \times \mathcal{V} \mapsto F$  on a field of scalars  $F \subseteq \mathbb{K}, K = \mathbb{R}$  or  $\mathbb{C}$  that satisfies:  
 $a(\alpha u + \beta v, w) = \alpha a(u, w) + \beta a(v, w)$   
 $a(u, \alpha v + \beta w) = \alpha a(u, v) + \beta a(u, w)$   
 $\forall u, v, w \in \mathcal{V}, \quad \forall \alpha, \beta \in \mathbb{K}$

**Thus:**  $a$  is linear w.r.t. each argument.

**Definition 16.14 Symmetric bilinear form:** A bilinear form  $a$  on  $\mathcal{V}$  is symmetric if and only if:  
 $a(u, v) = a(v, u) \quad \forall u, v \in \mathcal{V}$

**Definition 16.15 Positive (semi) definite bilinear form:**  
A symmetric bilinear form  $a$  on a vector space  $\mathcal{V}$  over a field  $F$  is **positive definite** if and only if:  
 $a(u, u) > 0 \quad \forall u \in \mathcal{V} \setminus \{0\}$   
And **positive semidefinite**  $\iff \geq$

**Corollary 16.1 Matrix induced Bilinear Form:**  
For finite dimensional inner product spaces  $\mathcal{X} \in \mathbb{K}^n$  any *symmetric* matrix  $A \in \mathbb{R}^{n \times n}$  induces a **bilinear form**:  
 $a(x, x') = x^\top A x' = (Ax')^\top x$

**Definition 16.16 Positive (semi) definite Matrix >:**  
A matrix  $A \in \mathbb{R}^{n \times n}$  is **positive definite** if and only if:  
 $x^\top A x > 0 \iff A > \quad \forall x \in \mathbb{R}^n \setminus \{0\}$   
And **positive semidefinite**  $\iff \geq$

**Corollary 16.2 Eigenvalues of positive (semi) definite matrix:**  
A positive definite matrix is a *symmetric matrix* where every eigenvalue is *strictly* positive and positive semi definite if every eigenvalue is *positive*.  
 $\forall \lambda_i \in \text{eigen}(\mathbf{A}) > 0$   
And **positive semidefinite**  $\iff \geq$

*Proof.* corollary 16.2 (for real matrices):  
Let  $v$  be an eigenvector of  $A$  then it follows:  
 $0 < \text{corollary 16.2} \quad v^\top A v = v^\top \lambda v = \|v\| \lambda$

**Corollary 16.3 Positive Definiteness and Determinant:**  
The determinant of a positive definite matrix is always positive. **Thus** a positive definite matrix is always *nonsingular*

**Definition 16.17 Negative (semi) definite Matrix <:**  
A matrix  $A \in \mathbb{R}^{n \times n}$  is **negative definite** if and only if:  
 $x^\top A x < 0 \iff A < 0 \quad \forall x \in \mathbb{R}^n \setminus \{0\}$   
And **negative semidefinite**  $\iff \leq$

**Theorem 16.2 Sylvester's criterion:** Let  $A$  be *symmetric/Hermitian* matrix and denote by  $A^{(k)}$  the  $k \times k$  upper left sub-matrix of  $A$ .  
Then it holds that:  
•  $A > 0 \iff \det(A^{(k)}) > 0 \quad k = 1, \dots, n$   
•  $A < 0 \iff (-1)^k \det(A^{(k)}) > 0 \quad k = 1, \dots, n$   
•  $A$  is indefinite if the first  $\det(A^{(k)})$  that breaks both of the previous patterns is on the wrong side.  
• Sylvester's criterion is inconclusive ( $A$  can be anything of the previous three) if the first  $\det(A^{(k)})$  that breaks both patterns is 0.

9. Inner Products

**Definition 16.18 Inner Product:** Let  $\mathcal{V}$  be a vector space over a field  $F \in \mathbb{K}$  of scalars. An inner product on  $\mathcal{V}$  is a map:  
 $\langle \cdot, \cdot \rangle : \mathcal{V} \times \mathcal{V} \mapsto F \subseteq \mathbb{K} \quad K = \mathbb{R}$  or  $\mathbb{C}$   
that satisfies:  
 $\forall x, y, z \in \mathcal{V}, \quad \alpha, \beta \in F$   
1. **(Conjugate) Stmmetry:**  $\langle x, y \rangle = \overline{\langle y, x \rangle}$ .  
2. **Linearity** in the first argument:  
 $\langle \alpha x + \beta y, z \rangle = \alpha \langle x, z \rangle + \beta \langle y, z \rangle$   
3. **Positive-definiteness:**  
 $\langle x, x \rangle \geq 0 : x = 0 \iff \langle x, x \rangle = 0$

**Definition 16.19 Inner Product Space  $(\mathcal{V}, \langle \cdot, \cdot \rangle_{\mathcal{V}})$ :** Let  $F \in \mathbb{K}$  be a field of scalars.  
An inner product space  $\mathcal{V}$  is a vector space over a field  $F$  together with an an **inner product**  $\langle \cdot, \cdot \rangle_{\mathcal{V}}$ .

**Corollary 16.4 Inner product  $\rightarrow$  S.p.d. Bilinear Form:**  
Let  $\mathcal{V}$  be a vector space over a field  $F \in \mathbb{K}$  of scalar.  
An **inner product** on  $\mathcal{V}$  is a positive definite symmetric bilinear form on  $\mathcal{V}$ .

**Example: scalar prodct**  
Let  $a(u, v) = u^\top I v$  then the standard scalar product can be defined in terms of a bilinear form vice versa the standard scalar product induces a bilinear form.

**Note**  
Inner products must be positive definite by definition  $\langle x, x \rangle \geq 0$ , whereas bilinear forms must not.

**Definition 16.20 Norm  $\|\cdot\|_{\mathcal{V}}$ :**  
A norm measures the **size** of its argument.  
**Formally** let  $\mathcal{V}$  be a vector space over a field  $F$ , a norm on  $\mathcal{V}$  is a map:  
 $\|\cdot\|_{\mathcal{V}} : \mathcal{V} \mapsto \mathbb{R}_+$   
that satisfies:  $\forall x, y \in \mathcal{V}, \quad \alpha \in F \subseteq \mathbb{K} \quad K = \mathbb{R}$  or  $\mathbb{C}$   
1. **Definitness:**  $\|x\|_{\mathcal{V}} = 0 \iff x = 0$ .  
2. **Homogeneity:**  $\|\alpha x\|_{\mathcal{V}} = |\alpha| \|x\|_{\mathcal{V}}$   
3. **Triangular Inequality:**  $\|x + y\|_{\mathcal{V}} \leq \|x\|_{\mathcal{V}} + \|y\|_{\mathcal{V}}$

Meaning: Triangular Inequality

States that for any triangle, the sum of the lengths of any two sides must be greater than or equal to the length of the remaining side.

**Corollary 16.5 Reverse Triangular Inequality:**  
 $-\|x - y\|_{\mathcal{V}} \leq \|x\|_{\mathcal{V}} - \|y\|_{\mathcal{V}} \leq \|x - y\|_{\mathcal{V}}$   
resp.  $|\|x\|_{\mathcal{V}} - \|y\|_{\mathcal{V}}| \leq \|x - y\|_{\mathcal{V}}$

Semi-norm

**Def.**

**Corollary 16.6 Normed vector space:** Is a vector space  $\mathcal{V}$  over a field  $F$ , on which a norm  $\|\cdot\|_{\mathcal{V}}$  can be defined.

**Corollary 16.7 Inner product induced norm  $\langle \cdot, \cdot \rangle_{\mathcal{V}} \rightarrow \|\cdot\|_{\mathcal{V}}$ :** Every inner product  $\langle \cdot, \cdot \rangle_{\mathcal{V}}$  induces a norm of the form:  
 $\|x\|_{\mathcal{V}} = \sqrt{\langle x, x \rangle} \quad x \in \mathcal{V}$

**Thus** We can define function spaces by their associated norm  $(\mathcal{V}, \|\cdot\|_{\mathcal{V}})$  and inner product spaces lead to normed vector spaces and vice versa.

**Corollary 16.8 Energy Norm:** A *s.p.d.* bilinear form  $a : \mathcal{V} \times \mathcal{V} \mapsto F$  induces an energy norm:  
 $\|x\|_a := (a(x, x))^{\frac{1}{2}} = \sqrt{a(x, x)} \quad x \in \mathcal{V}$

**Definition 16.21 Distance Function/Measure:** Is measuring the **distance** between two things.  
**Formally:** on a set  $S$  is a mapping:  
 $d(\cdot, \cdot) : S \times S \mapsto \mathbb{R}_+$   
that satisfies:  
 $\forall x, y, z \in S$   
1. **?**:  $d(x, x) = 0$   
2. **Symmetry:**  $d(x, y) = d(y, x)$   
3. **Triangular Identiy:**  $d(x, z) \leq d(x, y) + d(y, z)$

**Definition 16.22 Metric:** Is a distance measure that additionally satisfies:  
 $\forall x, y \in S$   
**identity of indiscernibles :**  $d(x, y) = 0 \iff x = y$

**Corollary 16.9 Metric  $\rightarrow$  Norm:** Every norm  $\|\cdot\|_{\mathcal{V}}$  on a vector space  $\mathcal{V}$  over a field  $F$  induces a metric by:  
 $d(x, y) = \|x - y\|_{\mathcal{V}} \quad \forall x, y \in \mathcal{V}$   
metric induced by norms additionally satisfy:  $\forall x, y \in \mathcal{V}, \quad \alpha \in F \subseteq \mathbb{K} \quad K = \mathbb{R}$  or  $\mathbb{C}$   
1. **Homogeneity/Scaling:**  $d(\alpha x, \alpha y)_{\mathcal{V}} = |\alpha| d(x, y)_{\mathcal{V}}$   
2. **Translational Invariance:**  $d(x + \alpha, y + \alpha) = d(x, y)$

Conversely not every metric induces a norm **but** if a metric  $d$  on a vector space  $\mathcal{V}$  satisfies the properties then it induces a norm of the form:

$$\|x\|_{\mathcal{V}} := d(x, 0)_{\mathcal{V}}$$

Note
Similarity measure is a much weaker notion than a metric as triangular inequality does not have to hold. <b>Hence:</b> If $a$ is similar to $b$ and $b$ is similar to $c$ it does not imply that $a$ is similar to $c$ .
Note
(bilinear form $\xrightarrow{\text{induces}}$ ) inner product $\xrightarrow{\text{induces}}$ norm $\xrightarrow{\text{induces}}$ metric.

10. Vector Algebra

10.1. Planes

https://math.stackexchange.com/questions/1485509/show-that-two-planes-are-parallel-and-find-the-distance-between-them

11. Derivatives

$$\begin{aligned} \frac{\partial}{\partial \mathbf{x}}(\mathbf{b}^\top \mathbf{x}) &= \frac{\partial}{\partial \mathbf{x}}(\mathbf{x}^\top \mathbf{b}) = \mathbf{b} \\ \frac{\partial}{\partial \mathbf{x}}(\mathbf{x}^\top \mathbf{x}) &= 2\mathbf{x} \\ \frac{\partial}{\partial \mathbf{x}}(\mathbf{x}^\top \mathbf{A} \mathbf{x}) &= (\mathbf{A}^\top + \mathbf{A})\mathbf{x} \quad \frac{\partial}{\partial \mathbf{x}}(\mathbf{b}^\top \mathbf{A} \mathbf{x}) = \mathbf{A}^\top \mathbf{b} \\ \frac{\partial}{\partial \mathbf{X}}(\mathbf{c}^\top \mathbf{X} \mathbf{b}) &= \mathbf{c} \mathbf{b}^\top \quad \frac{\partial}{\partial \mathbf{x}}(\|\mathbf{x} - \mathbf{b}\|_2) = \frac{\mathbf{x} - \mathbf{b}}{\|\mathbf{x} - \mathbf{b}\|_2} \\ \frac{\partial}{\partial \mathbf{x}}(\|\mathbf{x}\|_2^2) &= \frac{\partial}{\partial \mathbf{x}}(\mathbf{x}^\top \mathbf{x}) = 2\mathbf{x} \quad \frac{\partial}{\partial \mathbf{X}}(\|\mathbf{X}\|_F^2) = 2\mathbf{X} \\ \frac{\partial}{\partial \mathbf{x}}\|\mathbf{x}\|_1 &= \frac{\mathbf{x}}{|\mathbf{x}|} \\ \frac{\partial}{\partial \mathbf{x}}(\|\mathbf{A} \mathbf{x} - \mathbf{b}\|_2^2) &= 2(\mathbf{A}^\top \mathbf{A} \mathbf{x} - \mathbf{A}^\top \mathbf{b}) \quad \frac{\partial}{\partial \mathbf{X}}(|\mathbf{X}|) = |\mathbf{X}| \cdot \mathbf{X}^{-1} \\ \frac{\partial}{\partial x}(\mathbf{Y}^{-1}) &= -\mathbf{Y}^{-1} \frac{\partial \mathbf{Y}}{\partial x} \mathbf{Y}^{-1} \end{aligned}$$

12. Proofs

*Proof.*
<sup>[def. 16.9]</sup>

$$MM^{-1} = \begin{bmatrix} \mathbf{I}_{k,k} & \mathbf{0}_{k,l} \\ \mathbf{0}_{l,k} & \mathbf{I}_{l,l} \end{bmatrix} \tag{16.28}$$

□

Geometry

**Corollary 17.1 Affine Transformation in 1D:** Given: numbers  $x \in \hat{\Omega}$  with  $\hat{\Omega} = [a, b]$   
The **affine transformation** of  $\phi : \hat{\Omega} \rightarrow \Omega$  with  $y \in \Omega = [c, d]$  is defined by:

$$y = \phi(x) = \frac{d - c}{b - a} (x - a) + c \tag{17.1}$$

*Proof.* **corollary 17.1** By <sup>[def. 16.1]</sup> we want a function  $f : [a, b] \rightarrow [c, d]$  that satisfies:

$f(a) = c$                       **and**                       $f(b) = d$

additionally  $f(x)$  has to be a linear function (<sup>[def. 13.13]</sup>), that is the output scales the same way as the input scales.

Thus it follows:

$$\frac{d - c}{b - a} = \frac{f(x) - f(a)}{x - a} \quad \Longleftrightarrow \quad f(x) = \frac{d - c}{b - a} (x - a) + c$$

□

Trigonometry

**Law 17.1 Law of Cosine:** relates the side of a triangle to the cosine of its angles.

$$a^2 = b^2 + c^2 - 2bc \cos \theta_{b,c} \tag{17.2}$$

More general for vectors it holds:

$$\|\mathbf{x} - \mathbf{y}\|^2 = \|\mathbf{x}\|^2 + \|\mathbf{y}\|^2 - 2\|\mathbf{x}\|\|\mathbf{y}\| \cos \theta_{\mathbf{x},\mathbf{y}} \tag{17.3}$$

*Proof.* eq. (17.2):  
**We know:**  $\sin \theta = \frac{h}{b} \Rightarrow \underline{h} \quad \text{and} \quad \cos \theta = \frac{d}{b} \Rightarrow d$   
**Thus**  $\underline{e} = c - d = c - b \cos \theta \Rightarrow a^2 = \underline{e}^2 + \underline{h}^2 \Rightarrow a$      □

*Proof.* eq. (17.3):

$$\begin{aligned} \|\mathbf{x} - \mathbf{y}\|^2 &= (\mathbf{x} - \mathbf{y}) \cdot (\mathbf{x} - \mathbf{y}) \\ &= \mathbf{x} \cdot \mathbf{x} - 2\mathbf{x} \cdot \mathbf{y} + \mathbf{y} \cdot \mathbf{y} \\ &= \|\mathbf{x}\|^2 + \|\mathbf{y}\|^2 - 2(\|\mathbf{x}\|\|\mathbf{y}\| \cos \theta) \end{aligned}$$

□

**Law 17.2 Pythagorean theorem:** special case of ?? for right triangle:

$$a^2 = b^2 + c^2 \tag{17.4}$$

**Formula 17.1 Euler's Formula:**

$$e^{\pm ix} = \cos x \pm i \sin x \tag{17.5}$$

**Formula 17.2 Euler's Identity:**

$$e^{\pm i} = -1 \tag{17.6}$$

**Note**

$$e^n = 1 \Leftrightarrow n = i2\pi k, \quad k \in \mathbb{N} \tag{17.7}$$

**Sinh and Cosh**

$$\cosh x \stackrel{(13.37)}{=} \frac{1}{2} \left[ e^x + e^{-x} \right] = \cos(i x) \tag{17.10}$$
$$\sinh x \stackrel{(13.37)}{=} \frac{1}{2} \left[ e^x - e^{-x} \right] = -i \sin(i x) \tag{17.11}$$

**Note**

$$e^x = \cosh x + \sinh x \quad e^{-x} = \cosh x - \sinh x \tag{17.12}$$

**Note**

- $\cosh x$  is strictly positive.
- $\sinh x = 0$  has a unique root at  $x = 0$ .

**Theorem 17.1 Addition Theorems:**

$$\sin(\alpha \pm \beta) = \sin \alpha \cos \beta \pm \cos \alpha \sin \beta \tag{17.13}$$
$$\cos(\alpha \pm \beta) = \cos \alpha \cos \beta \mp \sin \alpha \sin \beta \tag{17.14}$$

**Werner Formulas**

$$\sin \alpha \cos \beta = \frac{1}{2} \left[ \sin(\alpha + \beta) + \sin(\alpha - \beta) \right] \tag{17.15}$$
$$\sin \alpha \sin \beta = \frac{1}{2} \left[ \cos(\alpha - \beta) - \cos(\alpha + \beta) \right] \tag{17.16}$$
$$\cos \alpha \cos \beta = \frac{1}{2} \left[ \cos(\alpha + \beta) + \cos(\alpha - \beta) \right] \tag{17.17}$$

**Note**

Using theorem 17.1 if follows:

$$\cos(\alpha \pm \pi) = -\cos \alpha \quad \text{and} \quad \sin(\alpha \pm \pi) = -\sin \alpha \tag{17.18}$$

Topology

Numerics

1. Machine Arithmetic's

1.1. Machine Numbers

**Definition 19.1 Institute of Electrical and Electronics Engineers (IEEE):** Is a engineering associations that defines a standard on how computers should treat machine numbers in order to have certain guarantees.

**Definition 19.2 Machine/Floating Point Numbers  $\mathbb{F}$ :** Computers are only capable to represent a *finite, discrete* set of the real numbers  $\mathbb{F} \subset \mathbb{R}$

**1.1.1. Floating Point Arithmetic's**  $x\tilde{\Omega}y = \mathfrak{fl}(x\Omega y)$

**Corollary 19.1 Closure:** Machine numbers  $\mathbb{F}$  are not *closed*<sup>[def. 11.6]</sup> under basic arithmetic operations:  
 $\mathbb{F} \Omega \mathbb{F} \mapsto \not\mathbb{F} \quad \Omega = \{+, -, *, /\}$  (19.1)

**Note**  
Corollary 19.1 provides a problem as the computer can only represent floating point number  $\mathbb{F}$ .

**Definition 19.3 Floating Point Operation  $\tilde{\Omega}$ :**  
Is a basic arithmetic operation that obtains a number  $x \in \mathbb{F}$  by applying a function rd:  
 $\mathbb{F} \tilde{\Omega} \mathbb{F} \mapsto \mathbb{F} \quad \tilde{\Omega} := \text{rd} \circ \Omega$  (19.2)  
 $\Omega = \{+, -, *, /\}$

**Definition 19.4 Rounding Function rd:**  
Given a real number  $x \in \mathbb{R}$  the rounding function replaces it by the nearest machine number  $\tilde{x} \in \mathbb{F}$ . If this is ambiguous (there are two possibilities), then it takes the larger one:  
 $\text{rd} : \begin{cases} \mathbb{R} \mapsto \mathbb{F} \\ x \mapsto \max \arg \min |x - \tilde{x}| \\ \tilde{x} \in \mathbb{F} \end{cases}$  (19.3)

**Consequence**  
Basic arithmetic rules such as associativity do no longer hold for operations such as addition and subtraction.  
**Axiom 19.1 Axiom of Round off Analysis:**  
Let  $x, y \in \mathbb{F}$  be (normalized) floats and assume that  $x\tilde{\Omega}y \in \mathbb{F}$  (i.e. no over/underflow). Then it holds that:  
 $x\tilde{\Omega}y = (x\Omega y)(1 + \delta) \quad \Omega = \{+, -, *, /\}$  (19.4)  
 $\tilde{f}(x) = f(x)(1 + \delta) \quad f \in \{\exp, \sin, \cos, \log, \dots\}$   
with  $|\delta| < \text{EPS}$

**Explanation 19.1** (axiom 19.1). *gives us a guarantee that for any two floating point numbers  $x, y \in \mathbb{F}$ , any operation involving them will give a floating point result which is within a factor of  $1 + \delta$  of the true result  $x\Omega y$ .*

**Finite**

**Definition 19.5 Overflow:** Result is bigger then the biggest representable floating point number.

**Definition 19.6 Underflow:** Result is smaller then the smaller representable floating point number i.e. to close to zero.

1.2. Roundoff Errors Log-Sum-Exp Trick

The sum exponential trick is at trick that helps to calculate the log-sum-exponential in a robust way by avoiding over/underflow. The log-sum-exponential<sup>[def. 19.7]</sup> is an expression that arises frequently in machine learning i.e. for the cross entropy loss or for calculating the evidence of a posterior prediction.  
The root of the problem is that we need to calculate the exponential  $\exp(x)$ , this comes with two different problems:  
• If  $x$  is large (i.e. 89 for single precision floats) then  $\exp(x)$  will lead to overflow  
• If  $x$  is very negative  $\exp(x)$  will lead to underflow/0. This is not necessarily a problem but if  $\exp(x)$  occurs in the denominator or the logarithm for example this is catastrophic.

**Definition 19.7 Log sum Exponential:**  
 $\text{LogSumExp}(x_1, \dots, x_n) := \log \left( \sum_{i=1}^n e^{x_i} \right)$  (19.5)

**Formula 19.1 Log-Sum-Exp Trick:**  
 $\log \left( \sum_{i=1}^n e^{x_i} \right) = a + \log \sum_{i=1}^n e^{x_i - a} \quad a := \max_{i \in \{1, \dots, n\}} x_i$  (19.6)

**Explanation 19.2** (formula 19.1). *The value  $a$  can be any real value but for robustness one usually chooses the max s.t.*  
• The leading digits are preserved by pulling out the maximum  $a$   
• Inside the log only zero or negative numbers are exponentiated, so there can be no overflow.  
• If there is underflow inside the log we know that at least the leading digits have been returned by the max.

*Proof.*  
$$\begin{aligned} \text{LSE} &= \log \left( \sum_{i=1}^n e^{x_i} \right) = \log \left( \sum_{i=1}^n e^{x_i - a} e^a \right) \\ &= \log \left( e^a \sum_{i=1}^n e^{x_i - a} \right) = \log \left( \sum_{i=1}^n e^{x_i - a} \right) + \log(e^a) \\ &= \log \left( \sum_{i=1}^n e^{x_i - a} \right) + a \end{aligned}$$

**Definition 19.8 Partition  $\Pi$ :**  
Given an interval  $[0, T]$  a sequence of values  $0 < t_0 < \dots < t_n < T$  is called a partition  $\Pi(t_0, \dots, t_n)$  of this interval.

1.3. Convergence for iterative methods

**Definition 19.9 Linear/Exponential Convergence:** A sequence  $\{x^{(k)}\}_k \in \mathbb{R}^n$  converges linearly to  $x^*$  if in the asymptotic limit  $k \rightarrow \infty$  it satisfies:  
 $\left\| x^{k+1} - x^* \right\| \leq \rho \left\| x^{(k)} - x^* \right\| \quad \rho \in (0, 1), \forall k \in \mathbb{N}_0$  (19.7)

**Exponential Convergence**  
Linear convergence is sometimes called exponential convergence. This is due to the fact that:  
1. We often have expressions of the form:  
 $\left\| x^{k+1} - x^* \right\| \leq \underbrace{(1 - \alpha)}_{:= \rho} \left\| x^{(k)} - x^* \right\|$   
2. and that  $(1 - \alpha) = \exp(-\alpha)$  from which follows that:  
eq. (19.8)  $\iff \left\| x^{k+1} - x^* \right\| \leq e^{-\alpha} \left\| x^{(k)} - x^* \right\|$

**Definition 19.10 Rate of Convergence:** Is a way to measure the rate of convergence of a sequence  $\{x^{(k)}\}_k \in \mathbb{R}^n$  to a value to  $x^*$ . Let  $\rho \in [0, 1]$  be the *rate of convergence* and define:

$$\lim_{k \rightarrow \infty} \frac{\left\| x^{k+1} - x^* \right\|}{\left\| x^{(k)} - x^* \right\|} = \rho \quad (19.8)$$

- $\rho = 1 \iff$  **Sublinear Rate** i.e. slower than linear
- $\rho \in (0, 1) \iff$  **Linear Rate**
- $\rho = 0 \iff$  **Superlinear Rate** i.e. faster then linear

**Definition 19.11 Convergence of order  $p$ :** In order to distinguish *superlinear convergence* we define the order of convergence.  
A sequence  $\{x^{(k)}\}_k \in \mathbb{R}^n$  converges superlinear with order  $p \in \{2, \dots\}$  to  $x^*$  if it satisfies:  
$$\lim_{k \rightarrow \infty} \frac{\left\| x^{k+1} - x^* \right\|}{\left\| x^{(k)} - x^* \right\|^p} = C \quad C < 1 \quad (19.9)$$

Does this even exist/check if this is true

**Definition 19.12 Exponential Convergence:** A sequence  $\{x^{(k)}\}_k \in \mathbb{R}^n$  converges exponentially with rate  $\rho$  to  $x^*$  if in the asymptotic limit  $k \rightarrow \infty$  it satisfies:  
 $\left\| x^{k+1} - x^* \right\| \leq \rho^k \left\| x^{(k)} - x^* \right\| \quad \rho < 1 \quad (19.10)$

1.4. Convention for discrization methods 2. Numerical Quadrature

**Definition 19.13 Order of a Quadrature Rule:** The order of a quadrature rule  $\mathcal{Q}_n : C^0([a, b]) \rightarrow \mathbb{R}$  is defined as:  
 $\text{order}(\mathcal{Q}_n) := \max \left\{ n \in \mathbb{N}_0 : \mathcal{Q}_n(p) = \int_a^b p(t) dt \quad \forall p \in \mathcal{P}_n \right\} + 1$  (19.11)

Thus it is the maximal degree+1 of polynomials (of degree maximal degree)  $\mathcal{P}$  maximal degree for which the quadrature rule yields exact results.

**Note**  
Is a quality measure for quadrature rules.

2.1. Composite Quadrature

**Definition 19.14 Composite Quadrature:**  
Given a mesh  $\mathcal{M} = \{a = x_0 < x_1 < \dots < x_m = b\}$  apply a Q.R.  $\mathcal{Q}_n$  to each of the mesh cells  $I_j := [x_{j-1}, x_j] \quad \forall j = 1, \dots, m \triangleq \text{p.w.}$  Quadrature:  
$$\int_a^b f(t) dt = \sum_{j=1}^m \int_{x_{j-1}}^{x_j} f(t) dt = \sum_{j=1}^m \mathcal{Q}_n(f|_{I_j}) \quad (19.12)$$

**Lemma 19.1 Error of Composite quadrature Rules:**  
Given a function  $f \in C^k([a, b])$  with integration domain:  
$$\sum_{i=1}^m h_i = |b - a| \quad \text{for } \mathcal{M} = \{x_j\}_{j=1}^m$$

Let:  $h_{\mathcal{M}} = \max_j |x_j, x_{j-1}|$  be the **mesh-width**  
Assume an equal number of quadrature nodes for each interval  $I_j = [x_{j-1}, x_j]$  of the mesh  $\mathcal{M}$  i.e.  $n_j = n$ .  
Then the error of a quadrature rule  $\mathcal{Q}_n(f)$  of order  $q$  is given by:  
$$\epsilon_n(f) = \mathcal{O} \left( n^{-\min\{k, q\}} \right) = \mathcal{O} \left( h_{\mathcal{M}}^{\min\{k, q\}} \right) \quad \text{for } n \rightarrow \infty$$
  
corollary 13.3  $\mathcal{O} \left( n^{-q} \right) = \mathcal{O} \left( h_{\mathcal{M}}^q \right) \quad \text{with } h_{\mathcal{M}} = \frac{1}{n}$  (19.13)

**Definition 19.15 Complexity  $W$ :** Is the number of function evaluations  $\triangleq$  number of quadrature points.  
 $W(\mathcal{Q}(f)_n) = \#f\text{-eval} \triangleq n$  (19.14)

**Lemma 19.2 Error-Complexity  $W(\epsilon_n(f))$ :** Relates the complexity to the quadrature error.  
**Assuming** and quadrature error of the form :  
$$\epsilon_n(f) = \mathcal{O}(n^{-q}) \iff \epsilon_n(f) = cn^{-q} \quad c \in \mathbb{R}_+$$
  
the error complexity is **algebraic** (??) and is given by:  
$$W(\epsilon_n(f)) = \mathcal{O}(\epsilon_n^{1/q}) = \mathcal{O}(\sqrt[q]{\epsilon_n}) \quad (19.15)$$

*Proof.* lemma 19.2: **Assume:** we want to reduce the error by a factor of  $\epsilon_n$  by increasing the number of quadrature points  $n_{\text{new}} = a \cdot n_{\text{old}}$ .  
**Question:** what is the additional effort ( $\#f\text{-eval}$ ) needed in order to achieve this reduction in error?  
$$\frac{c \cdot n_n^q}{c \cdot n_o^q} = \frac{1}{\epsilon_n} \Rightarrow n_n = n_o \cdot \sqrt[q]{\epsilon_n} = \mathcal{O}(\sqrt[q]{\epsilon_n}) \quad (19.16)$$

Optimization

**Definition 20.1 Fist Order Method:** A first-order method is an algorithm that chooses the  $k$ -th iterate in  
 $w_0 + \text{span}\{\nabla f(w_0), \dots, \nabla f(w_{k-1})\} \quad \forall k = 1, 2, \dots$  (20.1)

**Note**  
Gradient descent is a first order method

1. Lagrangian Optimization Theory

Add: derivation of lagrange function

**Definition 20.2 (Primal) Constraint Optimization:**  
Given an optimization problem with domain  $\Omega \subseteq \mathbb{R}^d$ :  
$$\begin{aligned} \min_{w \in \Omega} & f(w) \\ \text{s.t.} & g_i(w) \leq 0 \quad 1 \leq i \leq k \\ & h_j(w) = 0 \quad 1 \leq j \leq m \end{aligned}$$

**Definition 20.3 Lagrange Function:**  
$$\mathcal{L}(w, \alpha, \beta) := f(w) + \alpha g(w) + \beta h(w) \quad (20.2)$$

**Extremal Conditions**  
$$\begin{aligned} \nabla \mathcal{L}(w) &\stackrel{!}{=} 0 && \text{Extremal point } w^* \\ \frac{\partial}{\partial \beta} \mathcal{L}(w) &= h(w) \stackrel{!}{=} 0 && \text{Constraint satisfaction} \end{aligned}$$

For the inequality constraints  $g(w) \leq 0$  we distinguish two situations:  
Case I :  $g(w^*) < 0$  switch const. off  
Case II :  $g(w^*) \geq 0$  optimize using active eq. constr.  
$$\frac{\partial}{\partial \alpha} \mathcal{L}(w) = g(w) \stackrel{!}{=} 0 \quad \text{Constraint satisfaction}$$

**Definition 20.4 Lagrangian Dual Problem:** Is given by:  
Find  $\max_{w \in \Omega} \theta(\alpha, \beta) = \inf_{w \in \Omega} \mathcal{L}(w, \alpha, \beta)$   
s.t.  $\alpha_i \geq 0 \quad 1 \leq i \leq k$

**Solution Strategy**  
1. Find the extremal point  $w^*$  of  $\mathcal{L}(w, \alpha, \beta)$ :  
$$\frac{\partial \mathcal{L}}{\partial w} \Big|_{w=w^*} \stackrel{!}{=} 0 \quad (20.3)$$
  
2. Insert  $w^*$  into  $\mathcal{L}$  and find the extremal point  $\beta^*$  of the resulting dual Lagrangian  $\theta(\alpha, \beta)$  for the active constraints:  
$$\frac{\partial \theta}{\partial \beta} \Big|_{\beta=\beta^*} \stackrel{!}{=} 0 \quad (20.4)$$
  
3. Calculate the solution  $w^*(\beta^*)$  of the constraint minimization problem.

**Value of the Problem**  
**Value of the problem:** the value  $\theta(\alpha^*, \beta^*)$  is called the value of problem  $(\alpha^*, \beta^*)$ .

**Theorem 20.1 Upper Bound Dual Cost:** Let  $w \in \Omega$  be a feasible solution of the primal problem<sup>[def. 20.2]</sup> and  $(\alpha, \beta)$  a feasible solution of the respective dual problem<sup>[def. 20.4]</sup>.  
Then it holds that:  
$$f(w) \geq \theta(\alpha, \beta) \quad (20.5)$$

*Proof.*  
$$\begin{aligned} \theta(\alpha, \beta) &= \inf_{u \in \Omega} \mathcal{L}(u, \alpha, \beta) \leq \mathcal{L}(w, \alpha, \beta) \\ &= f(w) + \sum_{i=1}^k \underbrace{\alpha_i}_{\geq 0} g_i(w) + \sum_{j=1}^m \underbrace{\beta_j}_{\leq 0} \underbrace{h_j(w)}_{=0} \\ &\leq f(w) \end{aligned}$$

**Corollary 20.1 Duality Gap Corollary:** The value of the dual problem is upper bounded by the value of the primal problem:  
$$\sup \{\theta(\alpha, \beta) : \alpha \geq 0\} \leq \inf \{f(w) : g(w) \leq 0, h(w) = 0\} \quad (20.6)$$

**Theorem 20.2 Optimality:** The triple  $(w^*, \alpha^*, \beta^*)$  is a saddle point of the Lagrangian function for the primal problem, if and only if its components are optimal solutions of the primal and dual problems and if there is no duality gap, that is, the primal and dual problems having the same value:  
$$f(w^*) = \theta(\alpha^*, \beta^*) \quad (20.7)$$

**Definition 20.5 Convex Optimization:** Given: a **convex function**  $f$  and a **convex set**  $S$  solve:

$$\begin{aligned} \min_{\mathbf{x} \in S} f(\mathbf{x}) \end{aligned} \tag{20.8}$$

Often  $S$  is specified using linear inequalities:

e.g.  $S = \left\{ \mathbf{x} \in \mathbb{R}^d : \mathbf{A}\mathbf{x} \leq \mathbf{b} \right\}$

**Theorem 20.3 Strong Duality:** Given an convex optimization problem:

$$\begin{aligned} \min_{\mathbf{w} \in \Omega} f(\mathbf{w}) \\ \text{s.t.} \quad & g_i(\mathbf{w}) \leq 0 & 1 \leq i \leq k \\ & h_j(\mathbf{w}) = 0 & 1 \leq j \leq m \end{aligned}$$

where  $g_i, h_i$  can be written as affine functions:  $y(\mathbf{w}) = \mathbf{A}\mathbf{w} - \mathbf{b}$ .

Then it holds that the **duality gap** is zero and we obtain an optimal solution.

**Theorem 20.4 Kuhn-Tucker Conditions:** Given an optimization problem with convex domain  $\Omega \subseteq \mathbb{R}^d$ ,

$$\begin{aligned} \min_{\mathbf{w} \in \Omega} f(\mathbf{w}) \\ \text{s.t.} \quad & g_i(\mathbf{w}) \leq 0 & 1 \leq i \leq k \\ & h_j(\mathbf{w}) = 0 & 1 \leq j \leq m \end{aligned}$$

with  $f \in C^1$  convex and  $g_i, h_i$  affine.

**Necessary and sufficient conditions** for a normal point  $\mathbf{w}^*$  to be an optimum are the existence of  $\alpha^*, \beta^*$  s.t.:

$$\frac{\partial \mathcal{L}(\mathbf{w}, \alpha, \beta)}{\partial \mathbf{w}} \stackrel{!}{=} 0 \qquad \frac{\partial \mathcal{L}(\mathbf{w}^*, \alpha, \beta)}{\partial \beta} \stackrel{!}{=} 0 \tag{20.9}$$

under the conditions that:

- $\forall i_1, \dots, k \quad \alpha_i^* g_i(\mathbf{w}^*) = 0$ , s.t.:
  - Inactive Constraint:  $g_i(\mathbf{w}^*) < 0 \rightarrow \alpha_i = 0$ .
  - Active Constraint:  $g_i(\mathbf{w}^*) \nless 0 \rightarrow \alpha_i \geq 0 \quad \text{s.t.} \quad \alpha_i^* g_i(\mathbf{w}^*) = 0$

**Consequence**

We may become very sparce problems, if a lot of constraints are not actice  $\iff \alpha_i = 0$ .

Only a few points, for which  $\alpha_i > 0$  may affact the decision surface.

Stochastics

<b>Definition 20.6 Stochastics:</b> Is a collective term for the areas of <i>probability theory</i> and <i>statistics</i> .
<b>Definition 20.7 Statistics:</b> Is concerned with the analysis of data/experiments in order to draw conclusion of the underlying governing models that describe these experiments.
<b>Definition 20.8 Probability:</b> Is concerned with the quantification of the uncertainty of random experiments by use of statistical models. Hence it is the opposite of statistics.
<b>Definition 20.9 Probability:</b> Probability is the measure of the likelihood that an event will occur in a Random Experiment. Probability is quantified as a number between 0 and 1, where, loosely speaking, 0 indicates impossibility and 1 indicates certainty.
<div>Improve these definitions, maybe ask on quora/hilo</div> <b>Note: Stochastics vs. Stochastic</b> Stochastics is a noun and is a collective term for the areas of probability theory and statistics, while stochastic is an <i>adjective</i> , describing that a certain phenomena is governed by uncertainty i.e. a process.
<b>Probability Theory</b>
<b>Definition 21.1 Probability Space</b> $W = \{\Omega, \mathcal{F}, \mathbb{P}\}$ : Is the unique triple $\{\Omega, \mathcal{F}, \mathbb{P}\}$ , where $\Omega$ is its sample space, $\mathcal{F}$ its $\sigma$ -algebra of events, and $\mathbb{P}$ its probability measure.
<b>Definition 21.2 Sample Space <math>\Omega</math>:</b> Is the set of all possible outcomes (elementary events corollary 21.5) of an experiment see example 21.1
<b>Definition 21.3 Event</b> $A$ : An “event” is a subset of the sample space $\Omega$ and is a property which can be observed to hold or not to hold <i>after</i> the experiment is done (example 21.2). Mathematically speaking not every subset of $\Omega$ is an event and has an associated probability. Only those subsets of $\Omega$ that are part of the corresponding $\sigma$ -algebra $\mathcal{F}$ are events and have their assigned probability.
<b>Corollary 21.1 :</b> If the outcome $\omega$ of an experiment is in the subset $A$ , then the event $A$ is said to “have occurred”.
<b>Corollary 21.2 Complement Set</b> $A^C$ : is the contrary event of $A$ .
<b>Corollary 21.3 The Union Set</b> $A \cup B$ : Let $A, B$ be to evenest. The event “ $A$ or $B$ ” is interpreted as the union of both.
<b>Corollary 21.4 The Intersection Set</b> $A \cap B$ : Let $A, B$ be to evenest. The event “ $A$ and $B$ ” is interpreted as the intersection of both.
<b>Corollary 21.5 The Elementary Event</b> $\omega$ : Is a “singleton”, i.e. a subset $\{\omega\}$ containing a single outcome $\omega$ of $\Omega$ .
<b>Corollary 21.6 The Sure Event</b> $\Omega$ : Is equal to the sample space as it contains all possible elementary events.
<b>Corollary 21.7 The Impossible Event</b> $\emptyset$ : The impossible event i.e. nothing is happening is denoted by the empty set.
<b>Definition 21.4 The Family of All Events <math>\mathcal{A}/2^\Omega</math>:</b> The set of all subset of the sample space $\Omega$ called family of all events is given by the power set of the sample space $\mathcal{A} = 2^\Omega$ (for finite sample spaces).

<b>Definition 21.5 Probability</b> $\mathbb{P}(A)$ : Is a number associated with every $A$ , that measures the likelihood of the event to be realized “a priori”. The bigger the number the more likely the event will happen. 1. $0 \leq \mathbb{P}(A) \leq 1$ 2. $\mathbb{P}(\Omega) = 1$ 3. If $A \cap B = \emptyset$ then $\mathbb{P}(A \cup B) = \mathbb{P}(A) + \mathbb{P}(B)$
<b>Note</b> We can think of the probability of an event $A$ as the limit of the “frequency” of repeated experiments: $\mathbb{P}(A) = \lim_{n \rightarrow \infty} \frac{\delta(A)}{n} \quad \text{where} \quad \delta(A) = \begin{cases} 1 & \text{if } \omega \in A \\ 0 & \text{if } \omega \notin A \end{cases}$
<b>0.1. Sigma Algebras</b>
<b>Definition 21.6 Sigma Algebra <math>\sigma</math>:</b> A set $\mathcal{F}$ of subsets of $\Omega$ is called a $\sigma$ -algebra on $\Omega$ if the following properties apply <ul style="list-style-type: none"><li><math>\Omega \in \mathcal{F}</math> and <math>\emptyset \in \mathcal{F}</math></li><li>If <math>A \in \mathcal{F}</math> then <math>\Omega \setminus A = A^C \in \mathcal{F}</math>: The complementary subset of <math>A</math> is also in <math>\Omega</math>.</li><li>For all <math>A_i \in \mathcal{F} : \bigcup_{i=1} A_i \in \mathcal{F}</math></li></ul> See example 21.3.
<b>Corollary 21.8 <math>\mathcal{F}_{\min}</math>:</b> $\mathcal{F} = \{\emptyset, \Omega\}$ is the simplest $\sigma$ -algebra, telling us only if an event happened $\omega \in \Omega$ happened or not but not which one.
<b>Corollary 21.9 <math>\mathcal{F}_{\max}</math>:</b> $\mathcal{F} = 2^\Omega$ consists of all subsets of $\Omega$ and thus corresponds to full information i.e. we know if and which event happened.
<b>Definition 21.7 Measurable Space</b> $(\Omega, \mathcal{F})$ : Is the pair of a set and sigma algebra i.e. a sample space and sigma algebra $\{\Omega, \mathcal{F}\}$ .
<b>Corollary 21.10 <math>\mathcal{F}</math>-measurable Event:</b> The elements $A_i \in \mathcal{F}$ are called <i>measurable sets</i> or <i><math>\mathcal{F}</math>-measurable</i> .
<b>Interpretation</b> The $\sigma$ -algebra represents all of possible events of the experiment that we can detect. Thus we call the sets in $\mathcal{F}$ measurable sets/events. The sigma algebra is the mathematical construct that tells us how much information we obtain once we conduct some experiment.
<b>Definition 21.8 Sigma Algebra generated by a subset of <math>\Omega</math></b> $\sigma(\mathcal{C})$ : Let $\mathcal{C}$ be a class of subsets of $\Omega$ . The $\sigma$ -algebra generated by $\mathcal{C}$ , denoted by $\sigma(\mathcal{C})$ , is the <i>smallest</i> sigma algebra $\mathcal{F}$ that included all elements of $\mathcal{C}$ see example 21.4.
<b>Definition 21.9 Borel <math>\sigma</math>-algebra</b> $\mathcal{B}(\mathbb{R})$ : The Borel $\sigma$ -algebra $\mathcal{B}(\mathbb{R})$ is the smallest $\sigma$ -algebra containing all open intervals in $\mathbb{R}$ . The sets in contained in $\mathcal{B}(\mathbb{R})$ are called Borel sets. The extension to the multi-dimensional case, $\mathcal{B}(\mathbb{R}^n)$ , is straightforward. For all real numbers $a, b \in \mathbb{R}$ , $\mathcal{B}(\mathbb{R})$ contains various sets see example 21.5.
<b>Why do we need Borel Sets</b> So far we only looked at atomic events $\omega$ , with the help of sigma algebras we are now able to measure continuous events s.a. $[0, 1]$ .
<b>Corollary 21.11 :</b> The Borel $\sigma$ -algebra of $\mathbb{R}$ is generated by intervals of the form $(-\infty, a]$ , where $a \in \mathbb{Q}$ ( $\mathbb{Q}$ =rationals). See proof section 13.
<b>Definition 21.10 (<math>\mathbb{P}</math>)-trivial Sigma Algebra:</b> is a $\sigma$ -algebra $\mathcal{F}$ for which each event has a probability of zero or one: $\mathbb{P}(A) \in \{0, 1\} \quad \forall A \in \mathcal{F} \quad (21.1)$

<b>Interpretation</b> A trivial sigma algebra means that all events are almost surely constant and that there exist no non-trivial information. An example of a trivial sigma algebra is $\mathcal{F}_{\min} = \{\Omega, \emptyset\}$ .
<b>0.2. Measures</b>
<b>Definition 21.11 Measure</b> $\mu$ : A measure defined on a measurable space $\{\Omega, \mathcal{F}\}$ is a function/map: $\mu : \mathcal{F} \mapsto [0, \infty]$ for which holds: <ul style="list-style-type: none"><li><math>\mu(\emptyset) = 0</math></li><li>countable additivity [def. 21.12]</li></ul>
<b>Definition 21.12 Countable/<math>\sigma</math>-Additive Function:</b> Given a function $\mu$ defined on a $\sigma$ -algebra $\mathcal{F}$ . The function $\mu$ is said to be countable additive if for every countable sequence of pairwise disjoint elements $(F_i)_{i \geq 1}$ of $\mathcal{F}$ it holds that: $\mu\left(\bigcup_{i=1}^{\infty} F_i\right) = \sum_{i=1}^{\infty} \mu(F_i) \quad \text{for all} \quad F_j \cap F_k = \emptyset \quad \forall j \neq k \quad (21.3)$
<b>Corollary 21.12 Additive Function:</b> A function that satisfies countable additivity, is also additive, meaning that for every $F, G \in \mathcal{F}$ it holds: $\mu(F \cup G) = \mu(F) + \mu(G) \iff F \cap G = \emptyset \quad (21.4)$
<b>Intuition</b> If we take two event that cannot occur simultaneously, then the probability that at least one vent occurs is just the sum of the measure (probabilities) of the original events.
<b>Definition 21.13 Equivalent Measures</b> $\mu \sim \nu$ : Let $\mu$ and $\nu$ be two measures defined on a measurable space[def. 21.7] $(\Omega, \mathcal{F})$ . The two measures are said to be equivalent if it holds that: $\mu(A) > 0 \iff \nu(A) > 0 \quad \forall A \subseteq \mathcal{F} \quad (21.5)$ this is equivalent to $\mu$ and $\nu$ having equivalent null sets: $\mathcal{N}_\mu = \mathcal{N}_\nu \quad \begin{matrix} \mathcal{N}_\mu = \{A \in \mathcal{A}   \mu(A) = 0\} \\ \mathcal{N}_\nu = \{A \in \mathcal{A}   \nu(A) = 0\} \end{matrix} \quad (21.6)$ see example 21.6
<b>Definition 21.14 Measure Space</b> $\{\mathcal{F}, \Omega, \mu\}$ : The triplet of sample space, sigma algebra and a measure is called a measure space.
<b>Definition 21.15 Lebesgue Measure on <math>\mathcal{B}</math></b> $\lambda$ : Is the measure defined on the measurable space $\{\mathbb{R}, \mathcal{B}(\mathbb{R})\}$ which assigns the measure of each interval to be its length: $\lambda([a, b]) = b - a \quad (21.7)$
<b>Corollary 21.13 Lebesgue Measure of Atomitics:</b> <ul style="list-style-type: none"><li>The Lebesgue measure of a set containing only one point must be zero: <math display="block">\lambda(\{a\}) = 0 \quad (21.8)</math></li><li>The Lebesgue measure of a set containing countably many points <math>A = \{a_1, a_2, \dots, a_n\}</math> must be zero: <math display="block">\lambda(A) + \sum_{i=1}^n \lambda(\{a_i\}) = 0 \quad (21.9)</math></li><li>The Lebesgue measure of a set containing uncountably many points <math>A = \{a_1, a_2, \dots\}</math> can be either zero, positive and finite or infinite.</li></ul>
<b>0.3. Probability/Kolomogorov's Axioms</b> 1931
One problem we are still having is the range of $\mu$ , by standardizing the measure we obtain a well defined measure of events.
<b>Axiom 21.1 Non-negativity:</b> The probability of an event is a non-negative real number: If $A \in \mathcal{F}$ then $\mathbb{P}(A) \geq 0 \quad (21.10)$

<b>Axiom 21.2 Unitaarity:</b> The probability that at least one of the elementary events in the entire sample space $\Omega$ will occur is equal to one: The certain event $\mathbb{P}(\Omega) = 1 \quad (21.11)$
<b>Axiom 21.3 <math>\sigma</math>-additivity:</b> If $A_1, A_2, A_3, \dots \in \mathcal{F}$ are mutually disjoint, then: $\mathbb{P}\left(\bigcup_{i=1}^{\infty} A_i\right) = \sum_{i=1}^{\infty} \mu(A_i) \quad (21.12)$
<b>Corollary 21.14 :</b> As a consequence of this it follows: $\mathbb{P}(\emptyset) = 0 \quad (21.13)$
<b>Corollary 21.15 Complementary Probability:</b> $\mathbb{P}(A^C) = 1 - \mathbb{P}(A) \quad \text{with} \quad A^C = \Omega - A \quad (21.14)$
<b>Definition 21.16 Probability Measure</b> $\mathbb{P}$ : a probability measure is function $\mathbb{P} : \mathcal{F} \mapsto [0, 1]$ defined on a $\sigma$ -algebra $\mathcal{F}$ of a sample space $\Omega$ that satisfies the probability axioms.
<b>1. Conditional Probability</b>
<b>Definition 21.17 Conditional Probability:</b> Let $A, B$ be events, with $\mathbb{P}(B) \neq 0$ . Then the conditional probability of the event $A$ given $B$ is defined as: $\mathbb{P}(A B) = \frac{\mathbb{P}(A \cap B)}{\mathbb{P}(B)} \quad \mathbb{P}(B) \neq 0 \quad (21.15)$
<b>2. Independent Events</b>
<b>Theorem 21.1 Independent Events:</b> Let $A, B$ be two events. $A$ and $B$ are said to be independent iff: $\mathbb{P}(A \cap B) = \mathbb{P}(A)\mathbb{P}(B) \quad \begin{matrix} \mathbb{P}(A B) = \mathbb{P}(A), & \mathbb{P}(B) > 0 \\ \mathbb{P}(B A) = \mathbb{P}(B), & \mathbb{P}(A) > 0 \end{matrix} \quad (21.16)$
<b>Note</b> The requirement of no impossible events follows from [def. 21.17]
<b>Corollary 21.16 Pairwise Independent Evenest:</b> A finite set of events $\{A_i\}_{i=1}^n \in \mathcal{A}$ is <i>pairwise independent</i> if every pair of events is independent: $\mathbb{P}(A_i \cap A_j) = \mathbb{P}(A_i) \mathbb{P}(A_j) \quad i \neq j, \quad \forall i, j \in \mathcal{A} \quad (21.17)$
<b>Corollary 21.17 Mutal Independent Evenest:</b> A finite set of events $\{A_i\}_{i=1}^n \in \mathcal{A}$ is <i>mutal independent</i> if every event $A_j$ is independent of any intersection of the other events: $\mathbb{P}\left(\bigcap_{i=1}^k B_i\right) = \prod_{i=1}^k \mathbb{P}(B_i) \quad \begin{matrix} \forall \{B_i\}_{i=1}^k \subseteq \{A_i\}_{i=1}^n \\ k \leq n, \quad \{A_i\}_{i=1}^n \in \mathcal{A} \end{matrix} \quad (21.18)$
<b>3. Product Rule</b>
<b>Law 21.1 Product Rule:</b> Let $A, B$ be two events then the probability of both events occurring simultaneously is given by: $\mathbb{P}(A \cap B) = \mathbb{P}(B A)\mathbb{P}(A) = \mathbb{P}(A B)\mathbb{P}(B) \quad (21.19)$
<b>Law 21.2 Generalized Product Rule/Chain Rule:</b> is the generalization of the product rule?? to $n$ events $\{A_i\}_{i=1}^n$ $\mathbb{P}\left(\bigcap_{i=1}^k E_i\right) = \prod_{k=1}^n \mathbb{P}\left(E_k \middle  \bigcap_{i=1}^{k-1} E_i\right) = \quad (21.20)$ $= \mathbb{P}(E_n   E_{n-1} \cap \dots \cap E_1) \cdot \mathbb{P}(E_{n-1}   E_{n-2} \cap \dots \cap E_1) \dots \dots \mathbb{P}(E_3   E_2 \cap E_1) \mathbb{P}(E_2   E_1) \mathbb{P}(E_1)$

#### 4. Law of Total Probability

**Definition 21.18 Complete Event Field:** A complete event field  $\{A_i : i \in I \subseteq \mathbb{N}\}$  is a countable or finite partition of  $\Omega$  that is the partitions  $\{A_i : i \in I \subseteq \mathbb{N}\}$  are a *disjoint union* the sample space:

$$\bigcup_{i \in I} A_i = \Omega \quad A_i \cap A_j = \emptyset \quad i \neq j, \forall i, j \in I \quad (21.21)$$

##### Theorem 21.2

**Law of Total Probability/Partition Equation:** Let  $\{A_i : i \in I\}$  be a complete event field<sup>[def. 21.18]</sup> then it holds for  $B \in \mathcal{B}$ :

$$\mathbb{P}(B) = \sum_{i \in I} \mathbb{P}(B|A_i)\mathbb{P}(A_i) \quad (21.22)$$

#### 5. Bayes Theorem

**Law 21.3 Bayes Rule:** Let  $A, B$  be two events s.t.  $\mathbb{P}(B) > 0$  then it holds:

$$\mathbb{P}(A|B) = \frac{\mathbb{P}(B|A)\mathbb{P}(A)}{\mathbb{P}(B)} \quad \mathbb{P}(B) > 0 \quad (21.23)$$

follows directly from eq. (21.19).

**Theorem 21.3 Bayes Theorem:** Let  $\{A_i : i \in I\}$  be a complete event field<sup>[def. 21.18]</sup> and  $B \in \mathcal{B}$  a random event s.t.  $\mathbb{P}(B) > 0$ , then it holds:

$$\mathbb{P}(A_j|B) = \frac{\mathbb{P}(B|A_j)\mathbb{P}(A_j)}{\sum_{i \in I} \mathbb{P}(B|A_i)\mathbb{P}(A_i)} \quad (21.24)$$

proof section 13

#### Distributions on $\mathbb{R}$

##### 6.1. Distribution Function

**Definition 21.19 Distribution Function of  $\mathbb{P}$ :**  $F$ : The distribution function  $F$  induced by a probability  $\mathbb{P}$  on  $(\mathbb{R}, \mathcal{B})$  is the function:

$$F(x) = \mathbb{P}((-\infty, x]) \quad (21.25)$$

**Theorem 21.4 :** A function  $F$  is the distribution function of a (unique) probability on  $(\mathbb{R}, \mathcal{B})$  iff:

- $F$  is non-decreasing
- $F$  is right continuous
- $\lim_{x \rightarrow -\infty} F(x) = 0$  and  $\lim_{x \rightarrow +\infty} F(x) = 1$

**Corollary 21.18 :** A probability  $\mathbb{P}$  is uniquely determined by a distribution function  $F$ . That is if there exist another probability  $\mathbb{Q}$  s.t.

$$G(x) = \mathbb{Q}((-\infty, x])$$

and if  $F = G$  then it follows  $\mathbb{P} = \mathbb{Q}$ .

##### 6.2. Random Variables

A random variable  $X$  is a quantity that is not a variable in the classical sense but a variable with respect to the outcome of an experiment. Thus it is actually not a variable but a function/map.

Its value is determined in two steps:

- The outcome of an experiment is a random quantity  $\omega \in \Omega$
- The outcome  $\omega$  determines (possibly various) quantities of interests  $\iff$  random variables

Thus a random variable  $X$ , defined on a probability space  $\{\Omega, \mathcal{F}, \mathbb{P}\}$  is a mapping from  $\Omega$  into another space  $\mathcal{E}$ , usually  $\mathcal{E} = \mathbb{R}$  or  $\mathcal{E} = \mathbb{R}^n$ :

$$X : \Omega \mapsto \mathcal{E} \quad \omega \mapsto X(\omega)$$

Let now  $E \in \mathcal{E}$  be a quantity of interest, in order to quantify its probability we need to map it back to the original sample space  $\Omega$ :

Probability for an event in  $\Omega$

$$\mathbb{P}_X(E) = \mathbb{P}(\{\omega : X(\omega) \in E\}) = \mathbb{P}(X \in E) = \mathbb{P}(X^{-1}(E))$$

Probability for an event in  $E$

**Definition 21.20  $\mathcal{E}$ -measurable function:** Let  $(E, \mathcal{E})$  and  $(F, \mathcal{F})$  be two measurable spaces. A function  $f : E \mapsto F$  is called measurable (relative to  $\mathcal{E}$  and  $\mathcal{F}$ ) if

$$\forall B \in \mathcal{F} : f^{-1}(B) = \{\omega \in \mathcal{E} : f(\omega) \in B\} \in \mathcal{E} \quad (21.26)$$

##### Interpretation

The pre-image<sup>[def. 13.9]</sup> of  $B$  under  $f$  i.e.  $f^{-1}(B)$  maps all values of the target space  $F$  back to the sample space  $\mathcal{E}$  (for all possible  $B \in \mathcal{F}$ ).

**Definition 21.21 Random Variable:** A real-valued random variable (vector)  $X$ , defined on a probability space  $\{\Omega, \mathcal{E}, \mathbb{P}\}$  is an  $\mathcal{E}$ -measurable function mapping, if it maps its sample space  $\Omega$  into a target space  $(F, \mathcal{F})$ :

$$X : \Omega \mapsto \mathcal{F} \quad (\mathcal{F}^n) \quad (21.27)$$

Since  $X$  is  $\mathcal{E}$ -measurable it holds that  $X^{-1} : \mathcal{F} \mapsto \mathcal{E}$

**Corollary 21.19 :** Usually  $F = \mathbb{R}$ , which usually amounts to using the Borel  $\sigma$ -algebra  $\mathcal{B}$  of  $\mathbb{R}$ .

**Corollary 21.20 Random Variables of Borel Sets:** Given that we work with Borel  $\sigma$ -algebras then the definition of a random variable is equivalent to (due to corollary 21.11):

$$X^{-1}(B) = X^{-1}((-\infty, a]) = \{\omega \in \Omega : X(\omega) \leq a\} \in \mathcal{E} \quad \forall a \in \mathbb{R} \quad (21.28)$$

##### Definition 21.22

**Realization of a Random Variable**  $x = X(\omega)$ : Is the value of a random variable that is actually observed after an experiment has been conducted. In order to avoid confusion lower case letters are used to indicate actual observations/realization of a random variable.

##### Corollary 21.21 Indicator Functions

$I_A(\omega)$ : An important class of measurable functions that can be used as r.v. are indicator functions:

$$I_A(\omega) = \begin{cases} 1 & \text{if } \omega \in A \\ 0 & \text{if } \omega \notin A \end{cases} \quad (21.29)$$

We know that a probability measure  $\mathbb{P}$  on  $\mathbb{R}$  is characterized by the quantities  $\mathbb{P}((-\infty, a])$ . Thus the quantities.

**Corollary 21.22 :** Let  $(F, \mathcal{F}) = (\mathbb{R}, \mathcal{B})$  and let  $(E, \mathcal{E})$  and arbitrary measurable space. Let  $X$  be a real value function on  $E$ .

Then it holds that  $X$  is measurable if and only if  $\{X \leq a\} = \{\omega : X(\omega) \leq a\} = X^{-1}((-\infty, a]) \in \mathcal{E}$ , each  $a \in \mathbb{R}$  or  $\{X < a\} \in \mathcal{E}$ .

**Explanation 21.1** (corollary 21.22). A random variable is a function that is measurable if and only if its distribution function is defined.

##### 6.3. The Law of Random Variables

**Definition 21.23 Law/Distribution of  $X$**   $\mathcal{L}(X)$ : Let  $X$  be a r.v. on  $\{\Omega, \mathcal{F}, \mathbb{P}\}$ , with values in  $(E, \mathcal{E})$ , then the distribution/law of  $X$  is defined as:

$$\mathbb{P} : \mathcal{B} \mapsto [0, 1] \quad (21.30)$$

$$\mathbb{P}^X(B) = \mathbb{P}\{X \in B\} = \mathbb{P}(\omega : X(\omega) \in B) \quad \forall B \in \mathcal{E}$$

##### Note

- Sometimes  $\mathbb{P}^X$  is also called the *image* of  $\mathbb{P}$  by  $X$
- The law can also be written as:  
 $\mathbb{P}^X(B) = \mathbb{P}(X^{-1}(B)) = (\mathbb{P} \circ X^{-1})(B)$

**Theorem 21.5 :** The law/distribution of  $X$  is a probability measure  $\mathbb{P}$  on  $(E, \mathcal{E})$ .

##### Definition 21.24

**(Cumulative) Distribution Function**  $F_X$ : Given a real-valued r.v. then its cumulative distribution function is defined as:

$$F_X(x) = \mathbb{P}^X((-\infty, x]) = \mathbb{P}(X \leq x) \quad (21.31)$$

**Corollary 21.23 :** The distribution of  $\mathbb{P}^X$  of a real valued r.v. is entirely characterized by its cumulative distribution function  $F_X$ <sup>[def. 21.31]</sup>.

##### Property 21.1:

$$\mathbb{P}(X > x) = 1 - F_X(x) \quad (21.32)$$

##### Property 21.2: Probability of $X \in [a, b]$

$$\mathbb{P}(a < X \leq b) = F_X(b) - F_X(a) \quad (21.33)$$

##### 6.4. Probability Density Function

**Definition 21.25 Continuous Random Variable:** Is a r.v. for which a probability density function  $f_X$  exists.

**Definition 21.26 Probability Density Function:** Let  $X$  be a r.v. with associated cdf  $F_X$ . If  $F_X$  is continuously integrable for all  $x \in \mathbb{R}$  then  $X$  has a probability density  $f_X$  defined by:

$$F_X(x) = \int_{-\infty}^x f_X(y) dy \quad (21.34)$$

or alternatively:

$$f_X(x) = \lim_{\epsilon \rightarrow 0} \frac{\mathbb{P}(x \leq X \leq x + \epsilon)}{\epsilon} \quad (21.35)$$

**Corollary 21.24**  $\mathbb{P}(X = b) = 0$ ,  $\forall b \in \mathbb{R}$ :

$$\mathbb{P}(X = b) = \lim_{a \rightarrow b} \mathbb{P}(a < X \leq b) = \lim_{a \rightarrow b} \int_a^b f(x) dx = 0 \quad (21.36)$$

**Corollary 21.25 corollary 21.24:** From corollary 21.24 it follows that the exact borders are not necessary:

$$\mathbb{P}(a < X < b) = \mathbb{P}(a \leq X < b) = \mathbb{P}(a < X \leq b) = \mathbb{P}(a \leq X \leq b)$$

##### Corollary 21.26 :

$$\int_{-\infty}^{\infty} f(x) dx = 1 \quad (21.37)$$

##### Notes

- Often the cumulative distribution function is referred to as "cdf" or simply *distribution function*.
- Often the probability density function is referred to as "pdf" or simply *density*.

##### 6.5. Lebesgue Integration

###### Problems of Riemann Integration

- Difficult to extend to higher dimensions – general domains of definitions  $f : \Omega \mapsto \mathbb{R}$
- Depends on continuity
- Integration of limit processes require strong uniform convergence in order to integrate limit processes

$$\lim_{n \rightarrow \infty} \int f(x) dx \stackrel{\text{str. u.c.}}{=} \int \lim_{n \rightarrow \infty} f(x) dx$$

##### Idea

Partition domain by function values of equal size i.e. values that lie within the same sets/have the same value  $A_j$  build up the partitions w.r.t. to the variable  $x$ .

**Problem:** we do not know how big those sets/partitions on the  $x$ -axis will be.

**Solution:** we can use the measure  $\mu$  of our measure space  $\{\Omega, \mathcal{A}, \mu\}$  in order to obtain the size of our sets  $A_j \Rightarrow$  we do not have to care anymore about discontinuities, as we can measure the size of our sets using our measure.

##### Definition 21.27 Lebesgue Integral:

$$\lim_{n \rightarrow \infty} \sum_{i=1}^n c_i \mu(A_i) = \int_{\Omega} f d\mu \quad f(x) \approx c_i \quad \forall x \in A_i \quad (21.38)$$

##### Definition 21.28

**Simple Functions (Random Variables):** A r.v.  $X$  is called simple if it takes on only a finite number of values and hence can be written in the form:

$$X = \sum_{i=1}^n a_i \mathbb{I}_{A_i} \quad a_i \in \mathbb{R} \quad \mathcal{A} \ni A_i = \begin{cases} 1 & \text{if } \{X = a_i\} \\ 0 & \text{else} \end{cases} \quad (21.39)$$

##### 6.6. Independent Random Variables

We have seen that two events  $A$  and  $B$  are independent if knowledge that  $B$  has occurred does not change the probability that  $A$  will occur theorem 21.1.

For two random variables  $X, Y$  we want to know if knowledge of  $Y$  leaves the probability of  $X$ , to take on certain values unchanged.

##### Definition 21.29 Independent Random Variables:

Two real valued random variables  $X$  and  $Y$  are said to be independent iff:

$$\mathbb{P}(X \leq x | Y \leq y) = \mathbb{P}(X \leq x) \quad \forall x, y \in \mathbb{R} \quad (21.40)$$

which amounts to:

$$F_{X,Y}(x, y) = \mathbb{P}(\{X \leq x\} \cap \{Y \leq y\}) = \mathbb{P}(X \leq x, Y \leq y) = F_X(x)F_Y(y) \quad \forall x, y \in \mathbb{R} \quad (21.41)$$

or alternatively iff:

$$\mathbb{P}(X \in A, Y \in B) = \mathbb{P}(X \in A)\mathbb{P}(Y \in B) \quad \forall A, B \in \mathcal{B} \quad (21.42)$$

##### Note

If the joint distribution  $F_{X,Y}(x, y)$  can be factorized into two functions of  $x$  and  $y$  then  $X$  and  $Y$  are independent.

##### Definition 21.30

**Independent Identically Distributed:**

##### 7. Product Rule

**Law 21.4 Product Rule:** Let  $X, Y$  be two random variables then their jo

##### Law 21.5

**Generalized Product Rule/Chain Rule:**

##### 8. Change Of Variables Formula

###### Formula 21.1

**(Scalar Discret) Change of Variables:** Let  $X$  be a discret rv  $X \in \mathcal{X}$  with pmf  $\mathbb{P}_X$  and define  $Y \in \mathcal{Y}$  as  $Y = g(x)$  s.t.  $\mathcal{Y} = \{y | y = g(x), \forall x \in \mathcal{X}\}$ . **Where**  $g$  is an arbitrary strictly monotonic<sup>[def. 13.12]</sup> function.

**Let:**  $\mathcal{X}_y = x_i$  be the set of all  $x_i \in \mathcal{X}$  s.t.  $y = g(x_i)$ .

Then the pmf of  $Y$  is given by:

$$\mathbb{P}_Y(y) = \sum_{x_i \in \mathcal{X}_y} \mathbb{P}_X(x_i) = \sum_{x \in \mathcal{Y} : g(x) = y} \mathbb{P}_X(x) \quad (21.43)$$

see proof section 13

<b>Formula 21.2</b> <b>(Scalar Continuous) Change of Variables:</b> Let $X \sim f_X$ be a continuous r.v. and let $g$ be an arbitrary strictly monotonic <sup>[def. 13.12]</sup> function. Define a new r.v. $Y$ as $\mathcal{Y} = \{y y = g(x), \forall x \in \mathcal{X}\} \quad (21.44)$ then the pdf of $Y$ is given by: $f_Y(y) = f_X(x) \left  \frac{dx}{dy} \right  = f_X(x) \left  \frac{d}{dy} (g^{-1}(y)) \right  \quad (21.45)$ $= f_X(x) \frac{1}{\left  \frac{dy}{dx} \right } = \frac{f_X(g^{-1}(y))}{\left  \frac{dg}{dx}(g^{-1}(y)) \right } \quad (21.46)$	
--	--

<b>Formula 21.3</b> <b>(Continuous) Change of Variables:</b> Let $X = \{X_1, \dots, X_n\} \sim f_X$ be a continuous random vector and let $g$ be an arbitrary strictly monotonic <sup>[def. 13.12]</sup> function $g: \mathbb{R}^n \mapsto \mathbb{R}^m$  Define a new r.v. $Y$ as $\mathcal{Y} = \{y y = g(x), \forall x \in \mathcal{X}\} \quad (21.47)$ and let $h(x) := g(x)^{-1}$ then the pdf of $Y$ is given by: $\begin{aligned} f_Y(y) &= f_X(x_1, \dots, x_n) \cdot  J  \\ &= f_X(h_1(y), \dots, h_n(y)) \cdot  J  \\ &= f_X(y)  \det D_x h(x)  \Big _{x=y} \\ &= f_X(g^{-1}(y)) \left  \det \left( \frac{\partial g}{\partial x} \right) \right ^{-1} \end{aligned} \quad (21.48)$ where $J = \det Dh$ is the Jacobian <sup>[def. 14.4]</sup> . See also proof section 13 and example 21.8	
--	--

<b>Note</b> A monotonic function is required in order to satisfy inevitability.	
--	--

Probability Distributions on  $\mathbb{R}^n$   
 10. Joint Distribution

<b>Definition 21.31</b> <b>Joint (Cumulative) Distribution Function</b> $F_X$ : Let $X = (X_1, \dots, X_n)$ be a random vector in $\mathbb{R}^n$ , then its cumulative distribution function is defined as: $\begin{aligned} F_X(x) &= \mathbb{P}^X((-\infty, x]) = \mathbb{P}(X \leq x) \\ &= \mathbb{P}(X_1 \leq x_1, \dots, X_n \leq x_n) \end{aligned} \quad (21.49)$	
---	--

<b>Definition 21.32 Joint Probability Distribution:</b> Let $X = (X_1, \dots, X_n)$ be a random vector in $\mathbb{R}^n$ with associated cdf $F_X$ . If $F_X$ is continuously integrable for all $x \in \mathbb{R}$ then $X$ has a probability density $f_X$ defined by: $F_X(x) = \int_{-\infty}^{x_n} \dots \int_{-\infty}^{x_1} f_X(y_1, \dots, y_n) dy_1 \dots dy_n \quad (21.50)$ or alternatively: $f_X(x) = \lim_{\epsilon \rightarrow 0} \frac{\mathbb{P}(x_1 \leq X_1 \leq x_1 + \epsilon, \dots, x_n \leq X_n \leq x_n + \epsilon)}{\epsilon} \quad (21.51)$	
---	--

10.1. Marginal Distribution

<b>Definition 21.33 Marginal Distribution:</b>	
--	--

11. The Expectation

<b>Definition 21.34 Expectation:</b> $\mathbb{E}[X] = \int_{\Omega} X(\omega) \mathbb{P}(d\omega) = \int_{\Omega} X d\mathbb{P} \quad (21.52)$	
--	--

<b>Corollary 21.27 Expectation of simple r.v.:</b> If $X$ is a simple <sup>[def. 21.28]</sup> r.v. its expectation is given by: $\mathbb{E}[X] = \sum_{i=1}^n a_i \mathbb{P}(A_i) \quad (21.53)$	
---	--

<b>11.1. The Jensen Inequality</b> <b>Theorem 21.6 Jensen Inequality:</b> Let $X$ be a random variable and $g$ some function, then it holds: $\begin{aligned} g(\mathbb{E}[X]) &\geq \mathbb{E}[g(X)] & \text{if } g \text{ is convex} &^{\text{[def. 13.20]}} \\ g(\mathbb{E}[X]) &\leq \mathbb{E}[g(X)] & \text{if } g \text{ is concave} &^{\text{[def. 13.21]}} \end{aligned} \quad (21.54)$	
---	--

<b>11.2. Law of the Unconscious Statistician</b> <b>Law 21.6 Law of the Unconscious Statistician:</b> Let $X \in \mathcal{X}, Y \in \mathcal{Y}$ be random variables where $Y$ is defined as: $\mathcal{Y} = \{y y = g(x), \forall x \in \mathcal{X}\}$ then the expectation of $Y$ can be calculated in terms of $X$ : $\mathbb{E}_Y[y] = \mathbb{E}_X[g(x)] \quad (21.55)$	
---	--

<b>Consequence</b> Hence if we $\mathbf{p}_X$ we do not have to first calculate $\mathbf{p}_Y$ in order to calculate $\mathbb{E}_Y[y]$ .	
---	--

11.3. Properties  
 11.3.1. Linear Operators

<b>11.3.2. Quadratic Form</b> <b>Definition 21.35</b> proof 13 <b>Expectation of a Quadratic Form:</b> Let $\epsilon \in \mathbb{R}^n$ be a random vector with $\mathbb{E}[\epsilon] = \mu$ and $\mathbb{V}[\epsilon] = \Sigma$ : $\mathbb{E}[\epsilon^T A \epsilon] = \text{tr}(A \Sigma) + \mu^T A \mu \quad (21.56)$	
--	--

12. Moment Generating Function (MGF)

<b>Definition 21.36 Moment of Random Variable:</b> The $i$ -th moment of a random variable $X$ is defined as (if it exists): $m_i := \mathbb{E}[X^i] \quad (21.57)$	
---	--

<b>Definition 21.37</b> $\psi_X$ <b>Moment Generating Function (MGF):</b> $\psi_X(t) = \mathbb{E}[e^{tX}] \quad t \in \mathbb{R} \quad (21.58)$	
--	--

<b>Corollary 21.28 Sum of MGF:</b> The moment generating function of a sum of $n$ independent variables $(X_j)_{1 \leq j \leq n}$ is the product of the moment generating functions of the components: $\psi_{S_n}(t) = \psi_{X_1}(t) \dots \psi_{X_n}(t) \quad S_n := X_1 + \dots + X_n \quad (21.59)$	
---	--

<b>Corollary 21.29 :</b> The $i$ -th moment of a random variable is the $i$ -th derivative of its associated moment generating function evaluated zero: $\mathbb{E}[X^i] = \psi_X^{(i)}(0) \quad (21.60)$	
---	--

13. The Characteristic Function

Transforming probability distributions using the Fourier transform is a handy tool in probability in order to obtain properties or solve problems in another space before transforming them back.	
---	--

<b>Definition 21.38</b> $\hat{\mu}$ <b>Fourier Transformed Probability Measure:</b> $\hat{\mu} = \int e^{i\langle u, x \rangle} \mu(dx) \quad (21.61)$	
---	--

<b>Corollary 21.30 :</b> As $e^{i\langle u, x \rangle}$ can be rewritten using formulaeqs. (17.5) and (17.6) it follows: $\hat{\mu} = \int \cos(\langle u, x \rangle) \mu(dx) + i \int \sin(\langle u, x \rangle) \mu(dx) \quad (21.62)$	
--	--

where  $x \mapsto \cos(\langle x, u \rangle)$  and  $x \mapsto \sin(\langle x, u \rangle)$  are both bounded and Borel i.e. Lebesgue integrable.

<b>Definition 21.39 Characteristic Function</b> $\varphi_X$ : Let $X$ be an $\mathbb{R}^n$ -valued random variable. Its characteristic function $\varphi_X$ is defined on $\mathbb{R}^n$ as: $\varphi_X(u) = \int e^{i\langle u, x \rangle} \mathbb{P}^X(dx) = \widehat{\mathbb{P}^X}(u) \quad (21.63)$	
---	--

$$= \mathbb{E}[e^{i\langle u, x \rangle}] \quad (21.64)$$

<b>Corollary 21.31 :</b> The characteristic function $\varphi_X$ of a distribution always exists as it is equal to the Fourier transform of the probability measure, which always exists.	
---	--

<b>Note</b> This is an advantage over the moment generating function.	
--	--

<b>Theorem 21.7 :</b> Let $\mu$ be a probability measure on $\mathbb{R}^n$ . Then $\hat{\mu}$ is a bounded continuous function with $\hat{\mu}(0) = 1$ .	
--	--

<b>Theorem 21.8 Uniqueness Theorem:</b> The Fourier Transform $\hat{\mu}$ of a probability measure $\mu$ on $\mathbb{R}^n$ characterizes $\mu$ . That is, if two probability measures on $\mathbb{R}^n$ admit the same Fourier transform, they are equal.	
---	--

<b>Corollary 21.32 :</b> Let $X = (X_1, \dots, X_n)$ be an $\mathbb{R}^n$ -valued random variable. Then the real valued r.v.'s $(X_j)_{1 \leq j \leq n}$ are independent if and only if: $\varphi_X(u_1, \dots, u_n) = \prod_{j=1}^n \varphi_{X_j}(u_j) \quad (21.65)$	
--	--

<b>Proofs</b> <b>Proof.</b> corollary 21.11: Let $\mathcal{C}$ denote all open intervals. Since every open set in $\mathbb{R}$ is the countable union of open intervals <sup>[def. 11.8]</sup> , it holds that $\sigma(\mathcal{C})$ is the Borel $\sigma$ -algebra of $\mathbb{R}$ . Let $\mathcal{D}$ denote all intervals of the form $(-\infty, a]$ , $a \in \mathbb{Q}$ . Let $a, b \in \mathcal{C}$ , and let • $(a_n)_{n>1}$ be a sequence of rationals decreasing to $a$ and • $(b_n)_{n>1}$ be a sequence of rationals increasing strictly to $b$ $(a, b) = \bigcup_{n=1}^{\infty} (a_n, b_n] = \bigcup_{n=1}^{\infty} ((-\infty, b_n] \cap (-\infty, a_n]^C)$ Thus $\mathcal{C} \subset \sigma(\mathcal{D})$ , whence $\sigma(\mathcal{C}) \subset \sigma(\mathcal{D})$ but as each element of $\mathcal{D}$ is a closed subset, $\sigma(\mathcal{D})$ must also be contained in the Borel sets $\mathcal{B}$ with $\mathcal{B} = \sigma(\mathcal{C}) \subset \sigma(\mathcal{D}) \subset \mathcal{B}$	
--	--

<b>Proof.</b> theorem 21.3 Plug eq. (21.22) into the denominator and ?? into the nominator and then use <sup>[def. 21.17]</sup> : $\frac{\mathbb{P}(B A_j) \mathbb{P}(A_j)}{\sum_{i \in I} \mathbb{P}(B A_i) \mathbb{P}(A_i)} = \frac{\mathbb{P}(B \cap A_j)}{\mathbb{P}(B)} = \mathbb{P}(A_j B)$	
<b>Proof.</b> formula 21.1: $Y = g(X) \iff \mathbb{P}(Y = y) = \mathbb{P}(x \in \mathcal{X}_y) = \mathbf{p}_Y(y)$	

<b>Proof.</b> formula 21.2 (non-formal): The probability contained in a differential area must be invariant under a change of variables that is: $ f_Y(y) dy  =  f_X(x) dx $	
--	--

<b>Proof.</b> formula 21.2 (non-formal): The probability contained in a differential area must be invariant under a change of variables that is: $ f_Y(y) dy  =  f_X(x) dx $	
--	--

<b>Proof.</b> formula 21.2 from CDF: $\mathbb{P}(Y \leq y) = \mathbb{P}(g(X) \leq y) = \begin{cases} \mathbb{P}(X \leq g^{-1}(y)) & \text{if } g \text{ is increas.} \\ \mathbb{P}(X \geq g^{-1}(y)) & \text{if } g \text{ is decreas.} \end{cases}$	
---	--

If $g$ is monotonically increasing: $F_Y(y) = F_X(g^{-1}(y))$	
---	--

If $g$ is monotonically decreasing: $F_Y(y) = 1 - F_X(g^{-1}(y))$	
---	--

Now lets consider the probability for the continuous r.v.s: $\mathbb{P}(X \in B) = \int_x^{x+\Delta x} f_X(t) dt \xrightarrow{\Delta x \rightarrow 0}  \Delta x \cdot f_X(x) $	
--	--

For $y$ we use Taylor (??) $g(x + \Delta x) \stackrel{\text{eq. (13.41)}}{=} g(x) + \frac{dg}{dx} \Delta y \quad \text{for } \Delta x \rightarrow 0$ $= y + \Delta y \quad \text{with } \Delta y := \frac{dg}{dx} \cdot \Delta x \quad (21.66)$	
---	--

Thus for $\mathbb{P}(Y \in B')$ it follows: $\mathbb{P}(X \in B') = \int_y^{y+\Delta y} f_Y(t) dt \xrightarrow{\Delta y \rightarrow 0}  \Delta y \cdot f_Y(y) $ $= \left  \frac{dg}{dx}(x) \Delta x \cdot f_Y(y) \right $	
---	--

Now we simply need to related the surface of the two pdfs: $B = [x, x + \Delta x] \xrightarrow{\text{same surfaces}} [y, y + \Delta y] = B'$	
--	--

$\mathbb{P}(Y \in B) = \mathbb{P}(X \in B')$	
--	--

$\xrightarrow{\Delta y \rightarrow 0}  f_Y(y) \cdot \Delta y  = \left  f_Y(y) \cdot \frac{dg}{dx}(x) \Delta x \right  =  f_X(x) \cdot \Delta x $	
--	--

$f_Y(y) \cdot \left  \frac{dg}{dx}(x) \right   \Delta x  = f_X(x) \cdot  \Delta x $	
---	--

$\Rightarrow f_Y(y) = \frac{f_X(x)}{\left  \frac{dg}{dx}(x) \right } = \frac{f_X(g^{-1}(y))}{\left  \frac{dg}{dx} g^{-1}(y) \right }$	
---	--

<b>Proof.</b> <sup>[def. 21.35]</sup>	
---------------------------------------	--

$\begin{aligned} \mathbb{E}[\epsilon^T A \epsilon] &\stackrel{\text{eq. (16.13)}}{=} \mathbb{E}[\text{tr}(\epsilon^T A \epsilon)] \\ &\stackrel{\text{eq. (16.15)}}{=} \mathbb{E}[\text{tr}(A \epsilon \epsilon^T)] \\ &= \text{tr}(\mathbb{E}[A \epsilon \epsilon^T]) \\ &= \text{tr}(A \mathbb{E}[\epsilon \epsilon^T]) \\ &= \text{tr}(A(\Sigma + \mu \mu^T)) \\ &= \text{tr}(A \Sigma) + \text{tr}(A \mu \mu^T) \\ &\stackrel{\text{eq. (16.13)}}{=} \text{tr}(A \Sigma) + A \mu \mu^T \end{aligned}$	
---	--

Examples

<b>Example 21.1 :</b>	
-----------------------	--

- Toss of a coin (with head and tail):  $\Omega = \{H, T\}$ .
- Two tosses of a coin:  $\Omega = \{HH, HT, TH, TT\}$
- A cubic die:  $\Omega = \{\omega_1, \omega_2, \omega_3, \omega_4, \omega_5, \omega_6\}$
- The positive integers:  $\Omega = \{1, 2, 3, \dots\}$
- The reals:  $\Omega = \{\omega | \omega \in \mathbb{R}\}$

<b>Example 21.2 :</b>	
-----------------------	--

- Head in coin toss  $A = \{H\}$
- Odd number in die roll:  $A = \{\omega_1, \omega_3, \omega_5, \}$
- The integers smaller five:  $A = \{1, 2, 3, 4\}$

**Example 21.3 :** If the sample space is a die toss  $\Omega = \{\omega_1, \omega_2, \omega_3, \omega_4, \omega_5, \omega_6\}$ , the sample space may be that we are only told whether an even or odd number has rolled:  
 $\mathcal{F} = \{\emptyset, \{\omega_1, \omega_3, \omega_5\}, \{\omega_2, \omega_4, \omega_6\}\}$

**Example 21.4 :** If we are only interested in the subset-set  $\mathcal{A} \in \Omega$  of our experiment, then we can look at the corresponding generating  $\sigma$ -algebra  $\sigma(\mathcal{A}) = \{\emptyset, \mathcal{A}, \mathcal{A}^c, \Omega\}$ .

**Example 21.5 :**

- open half-lines:  $(-\infty, a)$  and  $(a, \infty)$ ,
- union of open half-lines:  $(a, b) = (-\infty, a) \cup (b, \infty)$ ,
- closed interval:  $[a, b] = \overline{(-\infty, a) \cup (b, \infty)}$ ,
- closed half-lines:  
 $(-\infty, a] = \bigcup_{n=1}^{\infty} [a - n, a]$  and  $[a, \infty) = \bigcup_{n=1}^{\infty} [a, a + n]$ ,
- half-open and half-closed  $(a, b] = (-\infty, b] \cap (a, \infty)$ ,
- every set containing only one real number:  
 $\{a\} = \bigcap_{n=1}^{\infty} (a - \frac{1}{n}, a + \frac{1}{n})$ ,
- every set containing finitely many real numbers:  
 $\{a_1, \dots, a_n\} = \bigcup_{k=1}^n \{a_k\}$ .

**Example 21.6 Equivalent (Probability) Measures:**

$$\Omega = \{1, 2, 3\} \quad \mathbb{P}(\{1, 2, 3\}) = \{2/3, 1/6, 1/6\}$$
$$\quad \quad \quad \tilde{\mathbb{P}}(\{1, 2, 3\}) = \{1/3, 1/3, 1/3\}$$

**Example 21.7 :**

add example fat book p.1286

add example prob th book 4

**Example 21.8 formula 21.2:** Let  $X, Y \stackrel{\text{ind.}}{\sim} \mathcal{N}(0, 1)$ .  
**Question:** proof that:  
 $U = X + Y \quad V = X - 1$   
are indepdent and normally distributed:

$$h(u, v) = \begin{cases} h_1(u, v) = \frac{u+v}{2} \\ h_2(u, v) = \frac{u-v}{2} \end{cases} \quad J = \det \begin{bmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & -\frac{1}{2} \end{bmatrix} = -\frac{1}{2}$$
$$\begin{aligned} f_{U,V} &= f_{X,Y}(x, y) \cdot \frac{1}{2} \\ &\stackrel{\text{indp.}}{=} f_X(x) \cdot f_Y(y) \\ &= \frac{1}{2} \cdot \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}} \cdot \frac{1}{\sqrt{2\pi}} e^{-\frac{y^2}{2}} \\ &= \frac{1}{2} \cdot \frac{1}{\sqrt{2\pi}} e^{-\left\{\left(\frac{u+v}{2}\right)^2 + \left(\frac{u-v}{2}\right)^2\right\}/2} \\ &= \frac{1}{\sqrt{2\pi}\sqrt{2}} e^{-\frac{u^2}{4}} \cdot \frac{1}{\sqrt{2\pi}\sqrt{2}} e^{-\frac{v^2}{4}} \end{aligned}$$

Thus  $U, V$  are independent r.v. distributed as  $\mathcal{N}(0, 2)$ .

## Combinatorics

### 0.1. Permutations

**Definition 22.1 Permutation  $n!$ :** Given a set<sup>[def. 11.1]</sup>  $S$  of  $n$  distinct objects, into how many distinct sequences/orders can we arrange/permutate those distinct objects  
 $P(S) = n! \iff P(S) = n \cdot (n-1) \cdot (n-2) \cdot \dots \cdot 1$   
(22.1)

If there exists multiple  $n_j$  objects of the same kind within  $S$  with  $j \in 1, \dots, n-1$  then we need to divide by those permutations:

$$P(S) = \frac{n!}{n_1! \cdot \dots \cdot n_k} \quad \text{s.t.} \quad \sum_{i=1}^k n_i \leq n \quad (22.2)$$

#### Note

This is because the sequence/order does not change if we exchange objects of the same kind (e.g. red ball by red ball).

## Statistics

Deletes/Move the following stuff appropriately

The probability that a discret random variable  $x$  is equal to some value  $\bar{x} \in \mathcal{X}$  is:

$$\mathbb{P}_x(\bar{x}) = \mathbb{P}(x = \bar{x})$$

add defint

**Definition 23.1 Almost Surely (a.s.):** Let  $(\Omega, \mathcal{F}, \mathbb{P})$  be a probability space. An event  $\omega \in \mathcal{F}$  happens almost surely iff  
 $\mathbb{P}(\omega) = 1 \iff \omega \text{ happens a.s.} \quad (23.1)$

**Definition 23.2 Probability Mass Function (PMF):**

**Definition 23.3 Discrete Random Variable (DVR):** The set of possible values  $\bar{x}$  of  $\mathcal{X}$  is countable of finite.  
 $\mathcal{X} = \{0, 1, 2, 3, 4, \dots, 8\} \quad \mathcal{X} = \mathbb{N} \quad (23.2)$

**Definition 23.4 Probability Density Function (PDF):** Is real function  $f: \mathbb{R}^n \rightarrow [0, \infty)$  that satisfies:

**Non-negativity:**  $f(x) \geq 0, \quad \forall x \in \mathbb{R}^n \quad (23.3)$

**Normalization:**  $\int_{-\infty}^{\infty} f(x) dx \stackrel{!}{=} 1 \quad (23.4)$

**Must be integrable**

**Note: why do we need probability density functions**

A continuous random variable  $X$  can realise an infinite count of real number values within its support  $B$  (as there are an infinitude of points in a line segment).  
Thus we have an infinitude of values whose sum of probabilities must equal one.

Thus these probabilities must each be zero otherwise we would obtain a probability of  $\infty$ . As we can not work with zero probabilities we use the next best thing, infinitesimal probabilities (defined as a limit).  
We say they are almost surely equal to zero:

$$\mathbb{P}(X = x) = 0 \quad \text{a.s.}$$

To have a sensible measure of the magnitude of these infinitesimal quantities, we use the concept of probability density, which yields a probability mass when integrated over an interval.

**Definition 23.5 Continuous Random Variable (CRV):** A real random variable (rrv)  $X$  is said to be (absolutely) continuous if there exists a pdf <sup>[def. 23.4]</sup>  $f_X$  s.t. for any subset  $B \subset \mathbb{R}$  it holds:

$$\mathbb{P}(X \in B) = \int_B f_X(x) dx \quad (23.6)$$

**Property 23.1 Zero Probability:** If  $X$  is a continuous rrv <sup>[def. 23.5]</sup>, then:

$$\mathbb{P}(X = a) = 0 \quad \forall a \in \mathbb{R} \quad (23.7)$$

**Property 23.2 Open vs. Closed Intervals:** For any real numbers  $a$  and  $b$ , with  $a < b$  it holds:

$$\begin{aligned} \mathbb{P}(a \leq X \leq b) &= \mathbb{P}(a \leq X < b) = \mathbb{P}(a < X \leq b) \\ &= \mathbb{P}(a < X < b) \end{aligned} \quad (23.8)$$

$\iff$  including or not the bounds of an interval does not modify the probability of a continuous rrv.

#### Note

Changing the value of a function at finitely many points has no effect on the value of a definite integral.

**Corollary 23.1 :** In particular for any real numbers  $a$  and  $b$  with  $a < b$ , letting  $B = [a, b]$  we obtain:

$$\mathbb{P}(a \leq X \leq b) = \int_a^b f_X(x) dx$$

**Proof.** Property 23.1:

$$\begin{aligned} \mathbb{P}(X = a) &= \lim_{\Delta x \rightarrow 0} \mathbb{P}(X \in [a, a + \Delta x]) \\ &= \lim_{\Delta x \rightarrow 0} \int_a^{a+\Delta x} f_X(x) dx = 0 \end{aligned}$$

□

**Proof.** Property 23.2:

$$\begin{aligned} \mathbb{P}(a \leq X \leq b) &= \mathbb{P}(a \leq X < b) = \mathbb{P}(a < X \leq b) \\ &= \mathbb{P}(a < X < b) = \int_a^b f_X(x) dx \end{aligned}$$

### 1.1. The Expectation

**Definition 23.10 Expectation (disc. case):**

$$\mu_X := \mathbb{E}_x[X] := \sum_{\bar{x} \in \mathcal{X}} \bar{x} \mathbb{P}_x(\bar{x}) \quad (23.14)$$

**Definition 23.11 Expectation (cont. case):**

$$\mathbb{E}_x[X] := \int_{\bar{x} \in \mathcal{X}} \bar{x} \mathbb{P}_x(\bar{x}) d\bar{x} \quad (23.15)$$

**Law 23.1 Expectation of independent variables:**

$$\mathbb{E}[XY] = \mathbb{E}[X] \mathbb{E}[Y] \quad (23.16)$$

**Property 23.4 Translation and scaling:** If  $X \in \mathbb{R}^n$  and  $Y \in \mathbb{R}^n$  are random vectors, and  $a, b, c \in \mathbb{R}^n$  are constants then it holds:

$$\mathbb{E}[a + bX + cY] = a + b\mathbb{E}[X] + c\mathbb{E}[Y] \quad (23.17)$$

Thus  $\mathbb{E}$  is a linear operator <sup>[def. 13.13]</sup>.

**Note: Expectation of the expectation**

The expectation of a r.v.  $X$  is a constant hence with Property 23.6 it follows:

$$\mathbb{E}[\mathbb{E}[X]] = \mathbb{E}[X] \quad (23.18)$$

**Property 23.5 Matrix×Expectation:** If  $X \in \mathbb{R}^n$  is a random vector and  $A \in \mathbb{R}^{m \times n}, B \in \mathbb{R}^{n \times m}$  are constant matrices then it holds:

$$\mathbb{E}[AXB] = A\mathbb{E}[(XB)] = A\mathbb{E}[X]B \quad (23.19)$$

**Proof.** eq. (23.24):

$$\begin{aligned} \mathbb{E}[XY] &= \sum_{x \in \mathcal{X}} \sum_{y \in \mathcal{Y}} \mathbb{P}_{X,Y}(x, y) xy \\ &\stackrel{??}{=} \sum_{x \in \mathcal{X}} \mathbb{P}_X(x) x \sum_{y \in \mathcal{Y}} \mathbb{P}_Y(y) y = \mathbb{E}[X] \mathbb{E}[Y] \end{aligned}$$

□

**Definition 23.12 Autocorrelation/Crosscorrelation  $\gamma(t_1, t_2)$ :** Describes the covariance <sup>[def. 23.16]</sup> between the two values of a stochastic process  $(X_t)_{t \in T}$  at different time points  $t_1$  and  $t_2$ .

$$\gamma(t_1, t_2) = \text{Cov}[X_{t_1}, X_{t_2}] = \mathbb{E}[(X_{t_1} - \mu_{t_1})(X_{t_2} - \mu_{t_2})] \quad (23.20)$$

For zero time differences  $t_1 = t_2$  the autocorrelation functions equals the variance:

$$\gamma(t, t) = \text{Cov}[X_t, X_t] \stackrel{\text{eq. (23.35)}}{=} \mathbb{V}[X_t] \quad (23.21)$$

#### Notes

- Hence** the autocorrelation describes the correlation of a function or signal with itself at a previous time point.
- Given** a random time dependent variable  $x(t)$  the autocorrelation function  $\gamma(t, t - \tau)$  describes how *similar* the time translated function  $x(t - \tau)$  and the original function  $x(t)$  are.
- If there exists some relation between the values of the time series that is non-random then the autocorrelation is non-zero.
- The autocorrelation is maximized/most similar for no translation  $\tau = 0$  at all.

**Definition 23.7 Cumulative distribution function (CDF):** Let  $(\Omega, \mathcal{F}, \mathbb{P})$  be a probability space.

The (cumulative) distribution function of a real-valued random variable  $X$  is the function given by:  
 $F_X(x) = \mathbb{P}(X \leq x) \quad \forall x \in \mathbb{R}$

**Property 23.3:**

$$\begin{aligned} \text{Monotonically Increasing} \quad x \leq y &\iff F_X(x) \leq F_X(y) \quad \forall x, y \in \mathbb{R} \\ \text{Upper Limit} \quad \lim_{x \rightarrow \infty} F_X(x) &= 1 \quad (23.11) \end{aligned}$$

$$\begin{aligned} \text{Lower Limit} \quad \lim_{x \rightarrow -\infty} F_X(x) &= 0 \quad (23.12) \end{aligned}$$

**Definition 23.8 CDF of a discret rv  $X$ :** Let  $X$  be discret rv with pdf  $\mathbb{P}_X$ , then the CDF of  $X$  is given by:

$$F_X(x) = \mathbb{P}(X \leq x) = \sum_{t=-\infty}^x \mathbb{P}_X(t)$$

**Definition 23.9 CDF of a continuous rv  $X$ :** Let  $X$  be continuous rv with pdf  $f_X$ , then the CDF of  $X$  is given by:

$$F_X(x) = \int_{-\infty}^x f_X(t) dt \iff \frac{\partial F_X(x)}{\partial x} = f_X(x)$$

**Lemma 23.1 Probability Interval:** Let  $X$  be a continuous rrv with pdf  $f_X$  and cumulative distribution function  $F_X$ , then it holds that:

$$\mathbb{P}(a \leq X \leq b) = F_X(b) - F_X(a) \quad (23.13)$$

**Proof.** <sup>[def. 23.9]</sup>:

$$F_X(x) = \mathbb{P}(X \leq x) = \mathbb{P}(X \in (-\infty, x)) = \int_{-\infty}^x f_X(t) dt$$

□

**Proof.** lemma 23.1:

$$\mathbb{P}(a \leq X \leq b) = \mathbb{P}(X \leq b) - \mathbb{P}(X \leq a)$$

or by the fundamental theorem of calculus (theorem 13.2):

$$\mathbb{P}(a \leq X \leq b) = \int_a^b f_X(t) dt = \int_a^b \frac{\partial F_X(t)}{\partial t} dt = [F_X(t)]_a^b$$

□

**Theorem 23.2 A continuous rv is fully characterized by its CDF:** A cumulative distribution function completely determines the distribution of a continuous real-valued random variable.

### 1. Key figures

## 2. Key Figures

### 2.1. The Expectation

**Definition 23.13 Expectation (disc. case):**

$$\mu_X := \mathbb{E}_x[x] := \sum_{\bar{x} \in \mathcal{X}} \bar{x} p_x(\bar{x}) \quad (23.22)$$

**Definition 23.14 Expectation (cont. case):**

$$\mathbb{E}_x[x] := \int_{\bar{x} \in \mathcal{X}} \bar{x} f_x(\bar{x}) d\bar{x} \quad (23.23)$$

**Law 23.2 Expectation of independent variables:**

$$\mathbb{E}[XY] = \mathbb{E}[X] \mathbb{E}[Y] \quad (23.24)$$

**Property 23.6 Translation and scaling:** If  $\mathbf{X} \in \mathbb{R}^n$  and  $\mathbf{Y} \in \mathbb{R}^n$  are random vectors, and  $a, b, c \in \mathbb{R}^n$  are constants then it holds:

$$\mathbb{E}[a + b\mathbf{X} + c\mathbf{Y}] = a + b\mathbb{E}[\mathbf{X}] + c\mathbb{E}[\mathbf{Y}] \quad (23.25)$$

Thus  $\mathbb{E}$  is a **linear** operator<sup>[def. 13.13]</sup>.

**Property 23.7 Affine Transformation of the Expectation:**

If  $\mathbf{X} \in \mathbb{R}^n$  is a random vector,  $\mathbf{A} \in \mathbb{R}^{m \times n}$  a constant matrix and  $b \in \mathbb{R}^m$  then it holds:

$$\mathbb{E}[\mathbf{A}\mathbf{X} + b] = \mathbf{A}\mu + b \quad (23.26)$$

**Note: Expectation of the expectation**

The expectation of a r.v.  $X$  is a constant hence with Property 23.6 it follows:

$$\mathbb{E}[\mathbb{E}[X]] = \mathbb{E}[X] \quad (23.27)$$

**Property 23.8 Matrix×Expectation:** If  $\mathbf{X} \in \mathbb{R}^n$  is a random vector and  $\mathbf{A} \in \mathbb{R}^{m \times n}$ ,  $\mathbf{B} \in \mathbb{R}^{n \times m}$  are constant matrices then it holds:

$$\mathbb{E}[\mathbf{A}\mathbf{X}\mathbf{B}] = \mathbf{A}\mathbb{E}[(\mathbf{X}\mathbf{B})] = \mathbf{A}\mathbb{E}[\mathbf{X}]\mathbf{B} \quad (23.28)$$

*Proof.* eq. (23.24):

$$\begin{aligned} \mathbb{E}[XY] &= \sum_{x \in \mathcal{X}} \sum_{y \in \mathcal{Y}} p_{X,Y}(x, y) xy \\ &\stackrel{??}{=} \sum_{x \in \mathcal{X}} p_X(x) x \sum_{y \in \mathcal{Y}} p_Y(y) y = \mathbb{E}[X] \mathbb{E}[Y] \end{aligned}$$

□

### 2.2. The Variance

**Definition 23.15 Variance  $\mathbb{V}[X]$ :** The variance of a random variable  $X$  is the expected value of the squared deviation from the expectation of  $X$  ( $\mu = \mathbb{E}[X]$ ). It is a measure of how much the actual values of a random variable  $X$  fluctuate around its executed value  $\mathbb{E}[X]$  and is defined by:

$$\mathbb{V}[X] := \mathbb{E}[(X - \mathbb{E}[X])^2] \stackrel{\text{see section 3}}{=} \mathbb{E}[X^2] - \mathbb{E}[X]^2 \quad (23.29)$$

#### 2.2.1. Properties

**Property 23.9 Variance of a Constant:** If  $a \in \mathbb{R}$  is a constant then it follows that its expected value is deterministic  $\Rightarrow$  we have no uncertainty  $\Rightarrow$  no variance:

$$\mathbb{V}[a] = 0 \quad \text{with} \quad a \in \mathbb{R} \quad (23.30)$$

see shift and scaling for proof section 3

**Property 23.10 Shifting and Scaling:**

$$\mathbb{V}[a + bX] = a^2 \sigma^2 \quad \text{with} \quad a \in \mathbb{R} \quad (23.31)$$

see section 3

**Property 23.11**

**Affine Transformation of the Variance:**

If  $\mathbf{X} \in \mathbb{R}^n$  is a random vector,  $\mathbf{A} \in \mathbb{R}^{m \times n}$  a constant matrix and  $b \in \mathbb{R}^m$  then it holds:

$$\mathbb{V}[\mathbf{A}\mathbf{X} + b] = \mathbf{A}\mathbb{V}[\mathbf{X}]\mathbf{A}^T \quad (23.32)$$

see section 3.

**Definition 23.16 Covariance:** The Covariance is a measure of how much two or more random variables vary **linearly** with each other.

$$\begin{aligned} \text{Cov}[X, Y] &= \mathbb{E}[(X - \mathbb{E}[X])(Y - \mathbb{E}[Y])] \\ &= \mathbb{E}[XY] - \mathbb{E}[X]\mathbb{E}[Y] \end{aligned} \quad (23.33)$$

see section 3

**Definition 23.17 Covariance Matrix:** The variance of a  $k$ -dimensional random vector  $\mathbf{X} = (X_1 \dots X_k)$  is given by a p.s.d. eq. (16.19) matrix called Covariance Matrix.

The Covariance is a measure of how much two or more random variables vary **linearly** with each other and the Variance on the diagonal is again a measure of how much a variable varies:

$$\begin{aligned} \mathbb{V}[\mathbf{X}] &:= \Sigma(\mathbf{X}) := \text{Cov}[\mathbf{X}, \mathbf{X}] := \\ &= \mathbb{E}[(\mathbf{X} - \mathbb{E}[\mathbf{X}])(\mathbf{X} - \mathbb{E}[\mathbf{X}])^T] \\ &= \mathbb{E}[\mathbf{X}\mathbf{X}^T] - \mathbb{E}[\mathbf{X}]\mathbb{E}[\mathbf{X}]^T \in [-\infty, \infty] \end{aligned} \quad (23.34)$$

$$\begin{aligned} &\begin{bmatrix} \mathbb{V}[X_1] & \dots & \text{Cov}[X_1, X_k] \\ \vdots & \ddots & \vdots \\ \text{Cov}[X_k, X_1] & \dots & \mathbb{V}[X_k] \end{bmatrix} \\ &= \begin{bmatrix} \mathbb{E}[(X_1 - \mu_1)(X_1 - \mu_1)] & \dots & \mathbb{E}[(X_1 - \mu_1)(X_k - \mu_k)] \\ \vdots & \ddots & \vdots \\ \mathbb{E}[(X_k - \mu_k)(X_1 - \mu_1)] & \dots & \mathbb{E}[(X_k - \mu_k)(X_k - \mu_k)] \end{bmatrix} \end{aligned}$$

**Note: Covariance and Variance**

The variance is a special case of the covariance in which two variables are identical:

$$\text{Cov}[X, X] = \mathbb{V}[X] \equiv \sigma^2(X) \equiv \sigma_X^2 \quad (23.35)$$

[add http://www.visiondummy.com/2014/04/geometric-interpretation-covariance-matrix/](http://www.visiondummy.com/2014/04/geometric-interpretation-covariance-matrix/)

**Property 23.12 Translation and Scaling:**

$$\text{Cov}(a + bX, c + dY) = bd\text{Cov}(X, Y) \quad (23.36)$$

**Property 23.13**

**Affine Transformation of the Covariance:**

If  $\mathbf{X} \in \mathbb{R}^n$  is a random vector,  $\mathbf{A} \in \mathbb{R}^{m \times n}$  a constant matrix and  $b \in \mathbb{R}^m$  then it holds:

$$\text{Cov}[\mathbf{A}\mathbf{X} + b] = \mathbf{A}\mathbb{V}[\mathbf{X}]\mathbf{A}^T = \mathbf{A}\Sigma(\mathbf{X})\mathbf{A}^T \quad (23.37)$$

**Definition 23.18 Correlation Coefficient:** Is the standardized version of the covariance:

$$\begin{aligned} \text{Corr}[\mathbf{X}] &:= \frac{\text{Cov}[\mathbf{X}]}{\sigma_{X_1} \dots \sigma_{X_k}} \in [-1, 1] \\ &= \begin{cases} +1 & \text{if } Y = aX + b \text{ with } a > 0, b \in \mathbb{R} \\ -1 & \text{if } Y = aX + b \text{ with } a < 0, b \in \mathbb{R} \end{cases} \end{aligned} \quad (23.38)$$

Figure 6: Several sets of  $(x, y)$  points, with their correlation coefficient

**Law 23.3 Translation and Scaling:**

$$\text{Corr}(a + bX, c + dY) = \text{sign}(b)\text{sign}(d)\text{Cov}(X, Y) \quad (23.39)$$

**Note**

- The correlation/covariance reflects the noisiness and direction of a linear relationship (top row fig. 6), **but** not the slope of that relationship (middle row fig. 6) nor many aspects of nonlinear relationships (bottom row)
- The set in the center of fig. 6 has a slope of 0 but in that case the correlation coefficient is undefined because the variance of  $Y$  is zero.
- Zero covariance/correlation  $\text{Cov}(X, Y) = \text{Corr}(X, Y) = 0$  implies that there does not exist a **linear** relationship between the random variables  $X$  and  $Y$ .

**Difference Covariance&Correlation**

- Variance is affected by scaling and covariance not ?? and law 23.3.
- Correlation is dimensionless, whereas the unit of the covariance is obtained by the product of the units of the two RV variables.

**Law 23.4 Covariance of independent RVs:** The covariance/correlation of two independent variable's (??) is zero:

$$\begin{aligned} \text{Cov}[X, Y] &= \mathbb{E}[XY] - \mathbb{E}[X]\mathbb{E}[Y] \\ &\stackrel{\text{eq. (23.24)}}{=} \mathbb{E}[X]\mathbb{E}[Y] - \mathbb{E}[X]\mathbb{E}[Y] = 0 \end{aligned}$$

**Zero covariance/correlation  $\nRightarrow$  independence**

$$\text{Cov}(X, Y) = \text{Corr}(X, Y) = 0 \nRightarrow p_{X,Y}(x, y) = p_X(x)p_Y(y)$$

**For example:** let  $X \sim \mathcal{U}([-1, 1])$  and let  $Y = X^2$ .

- Clearly  $X$  and  $Y$  are **dependent**
- But** the covariance/correlation between  $X$  and  $Y$  is non-zero:  

$$\begin{aligned} \text{Cov}(X, Y) &= \text{Cov}(X, X^2) = \mathbb{E}[X \cdot X^2] - \mathbb{E}[X]\mathbb{E}[X^2] \\ &= \mathbb{E}[X^3] - \mathbb{E}[X]\mathbb{E}[X^2] \stackrel{\text{eq. (23.61)}}{=} 0 - 0 \cdot \mathbb{E}[X^2] \\ &\stackrel{\text{eq. (23.50)}}{=} 0 \end{aligned}$$
 $\Rightarrow$  the relationship between  $Y$  and  $X$  must be non-linear.

**Definition 23.19 Quantile:** Are specific values  $q_\alpha$  in the range<sup>[def. 13.8]</sup> of a random variable  $X$  that are defined as the value for which the cumulative probability is less then  $\alpha \in (0, 1)$ :

$$q_\alpha : \mathbb{P}(X \leq x) = F_X(q_\alpha) = \alpha \xrightarrow{F \text{ invert.}} q_\alpha = F_X^{-1}(\alpha) \quad (23.40)$$

[add figures](#)

## 3. Proofs

*Proof.* eq. (23.29)

$$\begin{aligned} \mathbb{V}[X] &= \mathbb{E}[(X - \mathbb{E}[X])^2] = \mathbb{E}[X^2 - 2X\mathbb{E}[X] + \mathbb{E}[X]^2] \\ &\stackrel{\text{Property 23.6}}{=} \mathbb{E}[X^2] - 2\mathbb{E}[X]\mathbb{E}[X] + \mathbb{E}[X]^2 = \mathbb{E}[X^2] - \mu^2 \end{aligned}$$

□

*Proof.* Property 23.10

$$\begin{aligned} \mathbb{V}[a + bX] &= \mathbb{E}[(a + bX - \mathbb{E}[a + bX])^2] \\ &= \mathbb{E}[(a + bX - a - b\mathbb{E}[X])^2] \\ &= \mathbb{E}[(bX - b\mathbb{E}[X])^2] \\ &= \mathbb{E}[b^2(X - \mathbb{E}[X])^2] \\ &= b^2\mathbb{E}[(X - \mathbb{E}[X])^2] = b^2\sigma^2 \end{aligned}$$

□

*Proof.* Property 23.11

$$\begin{aligned} \mathbb{V}(\mathbf{A}\mathbf{X} + b) &= \mathbb{E}[(\mathbf{A}\mathbf{X} - \mathbb{E}[\mathbf{A}\mathbf{X}])^2] + 0 = \\ &= \mathbb{E}[(\mathbf{A}\mathbf{X} - \mathbb{E}[\mathbf{A}\mathbf{X}])(\mathbf{A}\mathbf{X} - \mathbb{E}[\mathbf{A}\mathbf{X}])^T] \\ &= \mathbb{E}[\mathbf{A}(\mathbf{X} - \mathbb{E}[\mathbf{X}])(\mathbf{A}(\mathbf{X} - \mathbb{E}[\mathbf{X}]))^T] \\ &= \mathbb{E}[\mathbf{A}(\mathbf{X} - \mathbb{E}[\mathbf{X}])(\mathbf{X} - \mathbb{E}[\mathbf{X}])^T \mathbf{A}^T] \\ &= \mathbf{A}\mathbb{E}[(\mathbf{X} - \mathbb{E}[\mathbf{X}])(\mathbf{X} - \mathbb{E}[\mathbf{X}])^T] \mathbf{A}^T = \mathbf{A}\mathbb{V}[\mathbf{X}]\mathbf{A}^T \end{aligned}$$

□

*Proof.* eq. (23.33)

$$\begin{aligned} \text{Cov}[X, Y] &= \mathbb{E}[(X - \mathbb{E}[X])(Y - \mathbb{E}[Y])] \\ &= \mathbb{E}[XY - X\mathbb{E}[Y] - \mathbb{E}[X]Y + \mathbb{E}[X]\mathbb{E}[Y]] \\ &= \mathbb{E}[XY] - \mathbb{E}[X]\mathbb{E}[Y] - \mathbb{E}[X]\mathbb{E}[Y] + \mathbb{E}[X]\mathbb{E}[Y] \\ &= \mathbb{E}[XY] - \mathbb{E}[X]\mathbb{E}[Y] \end{aligned}$$

□

Discrete Distributions

**Definition 23.20 Multivariate Distribution:** the variate refers to the number of input variables i.e. a m-variate distribution has m-input variables whereas a uni-variate distribution has only one.

Dimensional vs. Multivariate

The dimension refers to the number of dimensions we need to embed the function. If the variables of a function are independent than the dimension is the same as the number of inputs but the number of input variables can also be less.

4.1. Bernoulli Distribution Bern(p)

**Definition 23.21 Bernoulli Trial:** Is a random experiment with exactly two possible outcomes, success (1) and failure (0), in which the probability of success/failure is constant in every trial i.e. independent trials.

**Definition 23.22 Bernoulli Distribution**  $X \sim \text{Bern}(\mathbf{p})$ :  $X$  is a binary variable i.e. can only attain the values 0 (failure) or 1 (success) with a parameter  $\mathbf{p}$  that signifies the success probability:

$$\mathbf{p}(x; \mathbf{p}) = \begin{cases} \mathbf{p} & \text{for } x = 1 \\ 1 - \mathbf{p} & \text{for } x = 0 \end{cases} \iff \begin{cases} \mathbb{P}(X = 1) = \mathbf{p} \\ \mathbb{P}(X = 0) = 1 - \mathbf{p} \end{cases}$$
$$= \mathbf{p}^x \cdot (1 - \mathbf{p})^{1-x} \quad \text{for } x \in \{0, 1\}$$

$$\mathbb{E}[X] = \mathbf{p} \quad (23.41) \quad \mathbb{V}[X] = \mathbf{p}(1 - \mathbf{p}) \quad (23.42)$$

4.2. Binomial Distribution B(n, p)

**Definition 23.23 Binomial Distribution:** Models the probability of exactly  $X$  success given a fixed number  $n$ -Bernoulli experiments<sup>[def. 23.21]</sup>, where the probability of success of a single experiment is given by  $\mathbf{p}$ :

$$\mathbf{p}(x) = \binom{n}{x} \mathbf{p}^x (1 - \mathbf{p})^{n-x}$$

$n$  :nb. of repetitions  
 $x$  :nb. of successes  
 $\mathbf{p}$  :probability of success

$$\mathbb{E}[X] = n\mathbf{p} \quad (23.43) \quad \mathbb{V}[X] = n\mathbf{p}(1 - \mathbf{p}) \quad (23.44)$$

Note: Binomial Coefficient

The Binomial Coefficient corresponds to the permutation of two classes and not the variations as it seems from the formula.

Lets consider a box of  $n$  balls consisting of black and white balls. If we want to know the probability of drawing first  $x$  white and then  $n - x$  black balls we can simply calculate:

$$\underbrace{(\mathbf{p} \cdots \mathbf{p})}_{x\text{-times}} \cdot \underbrace{(q \cdots q)}_{n-x\text{-times}} = \mathbf{p}^x q^{n-x}$$

But there exists obviously further realization  $X = x$ , that correspond to permutations of the  $n$ -drawn balls.

There exist two classes of  $n_1 = x$ -white and  $n_2 = (n - x)$  black balls s.t.

$$P(n; n_1, n_2) = \frac{n!}{x!(n - x)!} = \binom{n}{x}$$

4.3. Geometric Distribution Geom(p)

**Definition 23.24 Geometric Distribution** $\text{Geom}(\mathbf{p})$ : Models the probability of the number  $X$  of Bernoulli trials<sup>[def. 23.21]</sup> until the first success

$$\mathbf{p}(x) = \mathbf{p}(1 - \mathbf{p})^{x-1}$$

$x$  :nb. of repetitions until first success  
 $\mathbf{p}$  :success probability of single Bernoulli experiment

$$F(x) = \sum_{i=1}^x \mathbf{p}(1 - \mathbf{p})^{i-1} \stackrel{??}{=} 1 - (1 - \mathbf{p})^x$$

$$\mathbb{E}[X] = \frac{1}{\mathbf{p}} \quad (23.45) \quad \mathbb{V}[X] = \frac{1 - \mathbf{p}}{\mathbf{p}^2} \quad (23.46)$$

Notes

- $\mathbb{E}[X]$  is the mean waiting time until the first success
- the number of trials  $x$  in order to have at least one success with a probability of  $\mathbf{p}(x)$ :

$$x \geq \frac{\mathbf{p}(x)}{1 - \mathbf{p}}$$

- $\log(1 - \mathbf{p}) \approx -\mathbf{p}$  for small  $\mathbf{p}$

4.4. Poisson Distribution Pois(λ)

**Definition 23.25 Poisson Distribution:** Is an extension of the binomial distribution, where the realization  $x$  of the random variable  $X$  may attain values in  $\mathbb{Z}_{\geq 0}$ .

It expresses the probability of a given number of events  $X$  occurring in a fixed interval if those events occur independently of the time since the last event.

$$\mathbf{p}(x) = e^{-\lambda} \frac{\lambda^x}{x!} \quad \begin{matrix} \lambda > 0 \\ x \in \mathbb{Z}_{\geq 0} \end{matrix} \quad (23.47)$$

**Event Rate**  $\lambda$ : describes the average number of events in a single interval.

$$\mathbb{E}[X] = \lambda \quad (23.48) \quad \mathbb{V}[X] = \lambda \quad (23.49)$$

Continuous Distributions

5.1. Uniform Distribution U(a, b)

**Definition 23.26 Uniform Distribution**  $\mathcal{U}(a, b)$ : Is probability distribution, where all intervals of the same length on the distribution's support<sup>[def. 23.6]</sup>  $\text{supp}(\mathcal{U}[a, b]) = [a, b]$  are equally probable/likely.

$$\mathbf{f}(x) = \frac{1}{b - a} \mathbb{1}_{x \in [a; b]} = \begin{cases} \frac{1}{b - a} = \text{const} & \text{if } a \leq x \leq b \\ 0 & \text{else} \end{cases} \quad (23.50)$$

$$F(x) = \begin{cases} 0 & x < a \\ \frac{x - a}{b - a} & \text{if } a \leq x \leq b \\ 1 & x > b \end{cases} \quad (23.51)$$

$$\mathbb{E}[X] = \frac{a + b}{2} \quad \mathbb{V}(X) = \frac{(b - a)^2}{12} \quad (23.52)$$

5.2. Exponential Distribution exp(λ)

**Definition 23.27 Exponential Distribution**  $X \sim \text{exp}(\lambda)$ : Is the continuous analogue to the geometric distribution<sup>[def. 23.24]</sup>.

It describes the probability  $\mathbf{f}(x; \lambda)$  that a continuous Poisson process (i.e., a process in which events occur continuously and independently at a constant average rate) will succeed/change state after a time interval  $x$ .

$$\mathbf{f}(x; \lambda) = \begin{cases} \lambda e^{-\lambda x} & \text{if } x \geq 0 \\ 0 & x < 0 \end{cases} \quad (23.53)$$

$$F(x; \lambda) = \begin{cases} 1 - e^{-\lambda x} & \text{if } x \geq 0 \\ 0 & x < 0 \end{cases} \quad (23.54)$$

$$\mathbb{E}[X] = \frac{1}{\lambda} \quad \mathbb{V}(X) = \frac{1}{\lambda^2} \quad (23.55)$$

5.3. Laplace Distribution

**Definition 23.28 Laplace Distribution:**

Laplace Distribution 
$$\mathbf{f}(x; \mu, \sigma) = \frac{1}{2\sigma} \exp\left(-\frac{|x - \mu|}{\sigma}\right) \quad (23.56)$$

5.4. The Normal Distribution N(μ, σ)

**Definition 23.29 Normal Distribution**  $X \sim \mathcal{N}(\mu, \sigma^2)$ : Is a symmetric distribution where the population parameters  $\mu, \sigma^2$  are equal to the expectation and variance of the distribution:

$$\mathbb{E}[X] = \mu \quad \mathbb{V}(X) = \sigma^2 \quad (23.57)$$

$$\mathbf{f}(x; \mu, \sigma^2) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left\{-\frac{1}{2}\left(\frac{x - \mu}{\sigma}\right)^2\right\} \quad (23.58)$$

$$F(x; \mu, \sigma^2) = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^x \exp\left\{-\frac{1}{2}\left(\frac{u - \mu}{\sigma}\right)^2\right\} du \quad (23.59)$$

$x \in \mathbb{R} \quad \text{or} \quad -\infty < x < \infty$

$$\varphi_X(u) = \exp\left\{iu\mu - \frac{u^2\sigma^2}{2}\right\} \quad (23.60)$$

Figure 8:  $\mu = 0, \sigma^2 = 0.2$   $\mu = 0, \sigma^2 = 1.0$   $\mu = 0, \sigma^2 = 5.0$   $\mu = -2, \sigma^2 = 0.5$

**Property 23.14:**  $\mathbb{P}_X(\mu - \sigma \leq x \leq \mu + \sigma) = 0.66$

**Property 23.15:**  $\mathbb{P}_X(\mu - 2\sigma \leq x \leq \mu + 2\sigma) = 0.95$

5.5. The Standard Normal distribution N(0, 1)

**Historic Problem:** the cumulative distribution eq. (23.59) does not have an analytical solution and numerical integration was not always computationally so easy. So how should people calculate the probability of  $x$  falling into certain ranges  $\mathbb{P}(x \in [a, b])$ ?

**Solution:** use a standardized form/set of parameters (by convention)  $\mathcal{N}_{0,1}$  and tabulate many different values for its cumulative distribution  $\phi(x)$  s.t. we can transform all families of Normal Distributions into the standardized version  $\mathcal{N}(\mu, \sigma^2) \xrightarrow{z} \mathcal{N}(0, 1)$  and look up the value in its table.

Definition 23.30

**Standard Normal Distribution**  $X \sim \mathcal{N}(0, 1)$ :

$$\mathbb{E}[X] = 0 \quad \mathbb{V}(X) = 1 \quad (23.61)$$

$$\mathbf{f}(x; 0, 1) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}x^2} \quad (23.62)$$

$$F(x; 0, 1) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{1}{2}u^2} du \quad (23.63)$$

$x \in \mathbb{R} \quad \text{or} \quad -\infty < x < \infty$

$$\psi_X(u) = e^{-\frac{u^2}{2}} \quad \varphi_X(u) = e^{-\frac{u^2}{2}} \quad (23.64)$$

Corollary 23.3

**Standard Normal Distribution Notation:** As the standard normal distribution is so commonly used people often use the letter  $Z$  in order to denote its the *standard* normal distribution and its  $\alpha$ -quantile<sup>[def. 23.19]</sup> is then denoted by:

$$z_\alpha = \Phi^{-1}(\alpha) \quad \alpha \in (0, 1) \quad (23.65)$$

5.5.1. Calculating Probabilities

**Property 23.16 Symmetry:** Let  $z > 0$

$$\mathbb{P}(Z \leq z) = \Phi(z) \quad (23.66)$$

$$\mathbb{P}(Z \leq -z) = \Phi(-z) = 1 - \Phi(z) \quad (23.67)$$

$$\mathbb{P}(-a \leq Z \leq b) = \Phi(b) - \Phi(-a) = \Phi(b) - (1 - \Phi(a))$$

$\stackrel{a=b=z}{=} 2\Phi(z) - 1 \quad (23.68)$

### 5.5.2. Linear Transformations of Normal Dist.

**Proposition 23.1 Linear Transformation** proof 1: Let  $X$  be a normally distributed random variable  $X \sim \mathcal{N}(\mu, \sigma^2)$ , then the linear transformed r.v.  $Y$  given by the affine transformation  $Y = a + bX$  with  $a \in \mathbb{R}, b \in \mathbb{R}_+$  follows:

$$Y \sim \mathcal{N}\left(a + b\mu, b^2\sigma^2\right) \iff f_Y(y) = \frac{1}{|b|} f_X\left(\frac{y-a}{b}\right) \quad (23.69)$$

**Proposition 23.2 Standardization:** Let  $X$  be a normally distributed random variable  $X \sim \mathcal{N}(\mu, \sigma^2)$ , then there exists a linear transformation  $Z = a + bX$  s.t.  $Z$  is a standard normally distributed random variable:

$$X \sim \mathcal{N}(\mu, \sigma^2) \xrightarrow[Z \sim \mathcal{N}(0, 1)]{Z = \frac{X - \mu}{\sigma}} \quad (23.70)$$

section 1

#### Note

If we know how many standard deviations our distribution is away from our target value then we can characterize it fully by the standard normal distribution.

**Proposition 23.3 Standardization of the CDF:** Let  $F_X(X)$  be the cumulative distribution function of a normally distributed random variable  $X \sim \mathcal{N}(\mu, \sigma^2)$ , then the cumulative distribution function  $\Phi_Z(z)$  of the standardized random normal variable  $Z \sim \mathcal{N}(0, 1)$  is related to  $F_X(X)$  by:

$$F_X(x) = \Phi\left(\frac{x - \mu}{\sigma}\right) \quad (23.71)$$

section 1

### 6. The Multivariate Normal distribution

**Definition 23.31 Multivariate Normal/Gaussian:** An  $\mathbb{R}^n$ -valued random variable  $\mathbf{X} = (X_1 \dots X_n)$  is *Multivariate Gaussian/Normal* if every linear combination of its components is a (one-dimensional) Gaussian:

$$\exists \mu, \sigma : \mathcal{L}\left(\sum_{i=1}^n \alpha_i X_j\right) = \mathcal{N}(\mu, \sigma^2) \quad \forall \alpha_i \in \mathbb{R} \quad (23.72)$$

(possible degenerated  $\mathcal{N}(0, 0)$  for  $\forall \alpha_j = 0$ )

#### Note

- Joint vs. multivariate:** a joint normal distribution can be a multivariate normal distribution or a product of univariate normal distributions **but**
- Multivariate refers to the number of variables that are placed as inputs to a function.

**Definition 23.32 Multivariate Normal distribution**  $X \sim \mathcal{N}_k(\mu, \Sigma)$ : A  $k$ -dimensional random vector

$$\mathbf{X} = (X_1 \dots X_n)^\top \quad \text{with} \quad \mu = (\mathbb{E}[x_1] \dots \mathbb{E}[x_k])^\top$$

and  $k \times k$  **p.s.d.** covariance matrix:

$$\Sigma := \mathbb{E}[(\mathbf{X} - \mu)(\mathbf{X} - \mu)^\top] = [\text{Cov}[x_i, x_j], 1 \leq i, j \leq k]$$

follows a  $k$ -dim multivariate normal/Gaussian distribution if its law<sup>[def. 21.23]</sup> satisfies:

$$f_{\mathbf{X}}(X_1, \dots, X_k) = \mathcal{N}(\mu, \Sigma) \quad (23.73)$$

$$= \frac{1}{\sqrt{(2\pi)^k \det(\Sigma)}} \exp\left(-\frac{1}{2}(\mathbf{X} - \mu)^\top \Sigma^{-1}(\mathbf{X} - \mu)\right)$$

Normalisation

$$\varphi_{\mathbf{X}}(\mathbf{u}) = \exp\left\{i\mathbf{u}^\top \mu - \frac{1}{2}\mathbf{u}^\top \Sigma \mathbf{u}\right\} \quad (23.74)$$

#### 6.1. Joint Gaussian Distributions

**Definition 23.33 Jointly Gaussian Random Variables:** Two random variables  $X, Y$  both scalars or vectors, are said to be **jointly Gaussian** if the joint vector random variable  $\mathbf{Z} = [X \ Y]^\top$  is again a GRV.

**Property 23.17 Joint Independent Gaussian Random Variables:** Let  $X_1, \dots, X_n$  be  $\mathbb{R}$ -valued independent random variables with laws  $\mathcal{N}(\mu_i, \sigma_i^2)$ . Then the law of  $\mathbf{X} = (X_1 \dots X_n)$  is a (multivariate) Gaussian distribution  $\mathbf{X} \sim \mathcal{N}(\mu, \Sigma)$  with:

$$\Sigma = \begin{bmatrix} \sigma_1^2 & 0 & \dots & 0 \\ 0 & \sigma_2^2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \sigma_n^2 \end{bmatrix} \quad \text{and} \quad \mu = \begin{bmatrix} \mu_1 \\ \mu_2 \\ \vdots \\ \mu_n \end{bmatrix} \quad (23.75)$$

**Corollary 23.4 Quadratic Form:**

If  $\mathbf{x}$  and  $\mathbf{y}$  are both independent GRVs

$$\mathbf{x} \sim \mathcal{N}(\mu_x, \Sigma_x) \quad \mathbf{y} \sim \mathcal{N}(\mu_y, \Sigma_y)$$

then they are jointly Gaussian<sup>[def. 23.33]</sup> given by:

$$\mathbf{p}(\mathbf{x}, \mathbf{y}) = \mathbf{p}(\mathbf{x})\mathbf{p}(\mathbf{y}) \quad (23.76)$$

$$\propto \exp\left(-\frac{1}{2}\left\{(\mathbf{x} - \mu_x)^\top \Sigma_x^{-1}(\mathbf{x} - \mu_x) + (\mathbf{y} - \mu_y)^\top \Sigma_y^{-1}(\mathbf{y} - \mu_y)\right\}\right)$$

$$= \exp\left(-\frac{1}{2}\left[(\mathbf{x} - \mu_x)^\top \quad (\mathbf{y} - \mu_y)^\top\right] \begin{bmatrix} \Sigma_x^{-1} & 0 \\ 0 & \Sigma_y^{-1} \end{bmatrix} \begin{bmatrix} \mathbf{x} - \mu_x \\ \mathbf{y} - \mu_y \end{bmatrix}\right)$$

$$\cong \exp\left(-\frac{1}{2}(\mathbf{z} - \mu_z)^\top \Sigma_z^{-1}(\mathbf{z} - \mu_z)\right)$$

**Property 23.18**

**Marginal Distribution of Multivariate Gaussian:** Let  $\mathbf{X} = (X_1 \dots X_n)^\top \sim \mathcal{N}(\mu, \Sigma)$  be an  $\mathbb{R}^n$  valued Gaussian and let  $V = \{1, 2, \dots, n\}$  be the index set of its variables. The  $k$ -variate marginal distribution of the Gaussian indexed by a subset of the variables:

$$\mathbf{A} = \{i_1, \dots, i_k\} \quad \mathbf{i}_j \in V \quad (23.77)$$

is given by:

$$\mathbf{X} = (X_{i_1} \dots X_{i_k})^\top \sim \mathcal{N}(\mu_A, \Sigma_{AA}) \quad (23.78)$$

$$\Sigma = \begin{bmatrix} \sigma_{i_1, i_1}^2 & \dots & \sigma_{i_1, i_k}^2 \\ \vdots & \ddots & \vdots \\ \sigma_{i_k, i_1}^2 & \dots & \sigma_{i_k, i_k}^2 \end{bmatrix} \quad \text{and} \quad \mu = \begin{bmatrix} \mu_{i_1} \\ \mu_{i_2} \\ \vdots \\ \mu_{i_k} \end{bmatrix}$$

#### 6.2. Conditional Gaussian Distributions

**Property 23.19 Conditional Gaussian Distribution:** Let  $\mathbf{X} = (X_1 \dots X_n)^\top \sim \mathcal{N}(\mu, \Sigma)$  be an  $\mathbb{R}^n$  valued Gaussian and let  $V = \{1, 2, \dots, n\}$  be the index set of its variables. Suppose we take two disjoint subsets of  $V$ :

$$\mathbf{A} = \{i_1, \dots, i_k\} \quad \mathbf{B} = \{j_1, \dots, j_m\} \quad \mathbf{i}_l, \mathbf{j}_{l'} \in V$$

then the conditional distribution of the random vector  $\mathbf{X}_A$ , conditioned on  $\mathbf{X}_B$  given by  $\mathbf{p}(\mathbf{X}_A | \mathbf{X}_B = \mathbf{x}_B)$  is:

$$\mathbf{X}_A = (X_{i_1} \dots X_{i_k})^\top \sim \mathcal{N}(\mu_{A|B}, \Sigma_{A|B}) \quad (23.79)$$

$$\mu_{A|B} = \mu_A + \Sigma_{AB} \Sigma_{BB}^{-1}(\mathbf{x}_B - \mu_B)$$

$$\Sigma_{A|B} = \Sigma_{AA} - \Sigma_{AB} \Sigma_{BB}^{-1} \Sigma_{BA}$$

#### Note

Can be proofed using the matrix inversion lemma but is a very tedious computation.

maybe add something

**Corollary 23.5**

**Conditional Distribution of Joint Gaussian's:** Let  $\mathbf{X}$  and  $\mathbf{Y}$  be jointly Gaussian random vectors:

$$\begin{bmatrix} \mathbf{X} \\ \mathbf{Y} \end{bmatrix} \sim \mathcal{N}\left(\begin{bmatrix} \mu_X \\ \mu_Y \end{bmatrix}, \begin{bmatrix} \mathbf{A} & \mathbf{C} \\ \mathbf{C}^\top & \mathbf{B} \end{bmatrix}\right) \quad (23.80)$$

then the *marginal* distribution of  $\mathbf{x}$  conditioned on  $\mathbf{y}$  can be written as:

$$\mathbf{X} \sim \mathcal{N}(\mu_{X|Y}, \Sigma_{X|Y})$$

$$\mu_{X|Y} = \mu_X + \mathbf{C}\mathbf{B}^{-1}(\mathbf{y} - \mu_Y)$$

$$\Sigma_{X|Y} = \mathbf{A} - \mathbf{C}\mathbf{B}^{-1}\mathbf{C}^\top \quad (23.81)$$

add proofs

### 6.3. Transformations

**Property 23.20 Multiples of Gaussian's**  $\mathbf{A}\mathbf{X}$ : Let  $\mathbf{X} = (X_1 \dots X_n)^\top \sim \mathcal{N}(\mu, \Sigma)$  be an  $\mathbb{R}^n$  valued Gaussian and let  $\mathbf{A} \in \mathbb{R}^{d \times n}$  then it follows:

$$\mathbf{Y} = \mathbf{A}\mathbf{X} \in \mathbb{R}^d \quad \mathbf{Y} \sim \mathcal{N}(\mathbf{A}\mu, \mathbf{A}\Sigma\mathbf{A}^\top) \quad (23.82)$$

**Property 23.21 Affine Transformation of GRVs:** Let  $\mathbf{y} \in \mathbb{R}^n$  be GRV,  $\mathbf{A} \in \mathbb{R}^{d \times n}$ ,  $\mathbf{b} \in \mathbb{R}^d$  and let  $\mathbf{x}$  be defined by the affine transformation<sup>[def. 16.1]</sup>:

$$\mathbf{x} = \mathbf{A}\mathbf{y} + \mathbf{b} \quad \mathbf{A} \in \mathbb{R}^{d \times n}, \mathbf{b} \in \mathbb{R}^d$$

Then  $\mathbf{x}$  is a GRV (see Section 1).

**Property 23.22 Linear Combination of jointly GRVs:** Let  $\mathbf{x} \in \mathbb{R}^n$ ,  $\mathbf{y} \in \mathbb{R}^m$  two jointly GRVs, and let  $\mathbf{z}$  be defined as:

$$\mathbf{z} = \mathbf{A}_x \mathbf{x} + \mathbf{A}_y \mathbf{y} \quad \mathbf{A}_x \in \mathbb{R}^{d \times n}, \mathbf{A}_y \in \mathbb{R}^{d \times m}$$

Then  $\mathbf{z}$  is GRV (see Section 1).

**Definition 23.34 Gaussian Noise:** Is statistical noise having a probability density function (PDF) equal to that of the normal/Gaussian distribution.

#### 6.4. Gamma Distribution $\Gamma(x, \alpha, \beta)$

**Definition 23.35 Gamma Distribution**  $X \sim \Gamma(x, \alpha, \beta)$ : Is a widely used distribution that is related to the exponential distribution, Erlang distribution, and chi-squared distribution as well as Normal distribution:

$$f(x; \alpha, \beta) = \begin{cases} \frac{\beta^\alpha}{\Gamma(\alpha)} x^{\alpha-1} e^{-\beta x} & \text{if } x > 0 \\ 0 & \text{if } x \leq 0 \end{cases} \quad (23.83)$$

$$\Gamma(\alpha) \stackrel{\text{eq. (13.66)}}{=} \int_0^\infty t^{\alpha-1} e^{-t} dt \quad (23.84)$$

with  $\alpha, \beta \in \mathbb{R}_{>0}$

#### 7. Student's t-distribution

**Definition 23.36 Student' t-distribution:**

add

##### 7.1. Delta Distribution

**Definition 23.37 The delta function  $\delta(\mathbf{x})$ :**

The delta/dirac function  $\delta(\mathbf{x})$  is defined by:

$$\int_{\mathbb{R}} \delta(\mathbf{x}) f(\mathbf{x}) d\mathbf{x} = f(0)$$

for any integrable function  $f$  on  $\mathbb{R}$ .

Or alternatively by:

$$\delta(\mathbf{x} - \mathbf{x}_0) = \lim_{\sigma \rightarrow 0} \mathcal{N}(\mathbf{x} | \mathbf{x}_0, \sigma) \quad (23.85)$$

$$\approx \infty \mathbb{1}_{\{\mathbf{x} = \mathbf{x}_0\}} \quad (23.86)$$

**Property 23.23 Properties of  $\delta$ :**

- Normalization:** The delta function integrates to 1:

$$\int_{\mathbb{R}} \delta(\mathbf{x}) d\mathbf{x} = \int_{\mathbb{R}} \delta(\mathbf{x}) \cdot c_1(\mathbf{x}) d\mathbf{x} = c_1(0) = 1$$

where  $c_1(\mathbf{x}) = 1$  is the constant function of value 1.

- Shifting:** 
$$\int_{\mathbb{R}} \delta(\mathbf{x} - \mathbf{x}_0) f(\mathbf{x}) d\mathbf{x} = f(\mathbf{x}_0) \quad (23.87)$$

- Symmetry:** 
$$\int_{\mathbb{R}} \delta(-\mathbf{x}) f(\mathbf{x}) d\mathbf{x} = f(0)$$

- Scaling:** 
$$\int_{\mathbb{R}} \delta(\alpha \mathbf{x}) f(\mathbf{x}) d\mathbf{x} = \frac{1}{|\alpha|} f(0)$$

#### Note

- In mathematical terms  $\delta$  is not a function but a **generalized function**.
- We may regard  $\delta(\mathbf{x} - \mathbf{x}_0)$  as a density with all its probability mass centered at the single point  $\mathbf{x}_0$ .
- Using a box/indicator function s.t. its surface is one and its width goes to zero, instead of a normal distribution eq. (23.85) would be a non-differentiable/discrete form of the dirac measure.

### Proofs

*Proof.* proposition 23.1: Let  $X$  be normally distributed with  $X \sim \mathcal{N}(\mu, \sigma^2)$ :

$$F_Y(y) \stackrel{y \geq 0}{=} \mathbb{P}_Y(Y \leq y) = \mathbb{P}(a + bX \leq y) = \mathbb{P}_X\left(X \leq \frac{y-a}{b}\right)$$

$$= F_X\left(\frac{y-a}{b}\right)$$

$$F_Y(y) \stackrel{y < 0}{=} \mathbb{P}_Y(Y \leq y) = \mathbb{P}(a + bX \leq y) = \mathbb{P}_X\left(X \geq \frac{y-a}{b}\right)$$

$$= 1 - F_X\left(\frac{y-a}{b}\right)$$

Differentiating both expressions w.r.t.  $y$  leads to:

$$f_Y(y) = \frac{dF_Y(y)}{dy} = \begin{cases} \frac{1}{b} \frac{dF_X\left(\frac{y-a}{b}\right)}{dy} \\ \frac{1}{-b} \frac{dF_X\left(\frac{y-a}{b}\right)}{dy} \end{cases} = \frac{1}{|b|} f_X(x) \left(\frac{y-a}{b}\right)$$

eq. (23.69)).

in order to prove that  $Y \sim \mathcal{N}(a + b\mu, b^2\sigma^2)$  we simply plug  $f_X$  in the previous expression:

$$f_Y(y) = \frac{1}{\sqrt{2\pi\sigma}|b|} \exp\left\{-\frac{1}{2}\left(\frac{y-a-\mu}{\sigma}\right)^2\right\}$$

$$= \frac{1}{\sqrt{2\pi\sigma}|b|} \exp\left\{-\frac{1}{2}\left(\frac{y-(a+b\mu)}{\sigma|b|}\right)^2\right\}$$

□

*Proof.* proposition 23.2: Let  $X$  be normally distributed with  $X \sim \mathcal{N}(\mu, \sigma^2)$ :

$$Z := \frac{X - \mu}{\sigma} = \frac{std}{std} X - \frac{\mu}{\sigma} = aX + b \quad \text{with } a = \frac{1}{\sigma}, b = -\frac{\mu}{\sigma}$$

eq. (23.69)  $\mathcal{N}(a\mu + b, a^2\sigma^2) \sim \mathcal{N}\left(\frac{\mu}{\sigma} - \frac{\mu}{\sigma}, \frac{\sigma^2}{\sigma^2}\right) \sim \mathcal{N}(0, 1)$

□

*Proof.* proposition 23.3: Let  $X$  be normally distributed with  $X \sim \mathcal{N}(\mu, \sigma^2)$ :

$$F_X(x) = \mathbb{P}(X \leq x) \stackrel{-\mu}{=} \mathbb{P}\left(\frac{X - \mu}{\sigma} \leq \frac{x - \mu}{\sigma}\right) \mathbb{P}\left(Z \leq \frac{x - \mu}{\sigma}\right)$$

$$= \Phi\left(\frac{x - \mu}{\sigma}\right)$$

□

*Proof.* Property 23.21 scalar case

Let  $\mathbf{y} \sim \mathbf{p}(\mathbf{y}) = \mathcal{N}(\mu, \sigma^2) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(y-\mu)^2}{2\sigma^2}\right)$  and

define  $\mathbf{x} = a\mathbf{y} + b$   $a \in \mathbb{R}_+, b \in \mathbb{R}$

Using the Change of variables formula it follows:

$$\mathbf{p}_x(\bar{x}) \stackrel{??}{=} \frac{\mathbf{p}_y(\bar{y})}{\left|\frac{d\mathbf{x}}{d\mathbf{y}}\right|} \stackrel{\bar{y} = \frac{\bar{x}-b}{a}}{=} \frac{1}{a} \frac{1}{\sqrt{2\pi\mu^2}} \exp\left(-\frac{1}{2\sigma^2}\left(\frac{\bar{x}-b}{a} - \mu\right)^2\right)$$

$$= \frac{1}{\sqrt{2\pi a^2 \mu^2}} \exp\left(-\frac{1}{2\sigma^2 a^2}(\bar{x} - b - a\mu)^2\right)$$

$\mu_x$

Then  $\mathbf{x} \sim \mathcal{N}(\mu_x, \sigma_x^2) = \mathcal{N}(a\mu + b, a^2\sigma^2)$

□

#### Note

We can also verify that we have calculated the right mean and variance by:

$$\mathbb{E}[x] = \mathbb{E}[a\mathbf{y} + b] = a\mathbb{E}[y] + b = a\mu + b$$

$$\mathbb{V}[x] = \mathbb{V}[a\mathbf{y} + b] = a^2\mathbb{V}[y] = a^2\sigma^2$$

Proof. ??

$$\begin{aligned}
 \mathbb{P}_{\mathbf{X}}(\mathbf{u}) &= \prod_i^n \mathbb{P}_{X_i}(u_i) \\
 &= \prod_{i=1}^n \frac{1}{\sqrt{2\pi\sigma_i^2}} \exp\left(-\frac{(x_i - \mu_i)^2}{2\sigma_i^2}\right) \\
 \varphi_{\mathbf{X}}(\mathbf{u}) &= \exp\left\{iu_1\mu_1 - \frac{1}{2}\sigma_1u_1^2\right\} \cdots \exp\left\{iu_n\mu_n - \frac{1}{2}\sigma_nu_n^2\right\} \\
 &= \exp\left\{i\sum_i^n u_n\mu_n - \frac{1}{2}\sum_i^n \sigma_nu_n^2\right\} = \exp\left\{i\mathbf{u}^\top \boldsymbol{\mu} - \frac{1}{2}\mathbf{u}\boldsymbol{\Sigma}\mathbf{u}\right\}
 \end{aligned}$$

□

Proof. Property 23.22

From Property 23.21 it follows immediately that  $\mathbf{z}$  is GRV

$\mathbf{z} \sim \mathcal{N}(\boldsymbol{\mu}_z, \boldsymbol{\Sigma}_z)$  with:

$\mathbf{z} = \mathbf{A}\boldsymbol{\xi}$  with  $\mathbf{A} = \begin{bmatrix} \mathbf{A}_x & \mathbf{A}_y \end{bmatrix}$  and  $\boldsymbol{\xi} = \begin{pmatrix} \mathbf{x} & \mathbf{y} \end{pmatrix}$

Knowing that  $\mathbf{z}$  is a GRV it is sufficient to calculate  $\boldsymbol{\mu}_z$  and  $\boldsymbol{\Sigma}_z$  in order to characterize its distribution:

$$\begin{aligned}
 \mathbb{E}[\mathbf{z}] &= \mathbb{E}[\mathbf{A}_x\mathbf{x} + \mathbf{A}_y\mathbf{y}] = \mathbf{A}_x\boldsymbol{\mu}_x + \mathbf{A}_y\boldsymbol{\mu}_y \\
 \mathbb{V}[\mathbf{z}] &= \mathbb{V}[\mathbf{A}\boldsymbol{\xi}] \stackrel{??}{=} \mathbf{A}\mathbb{V}[\boldsymbol{\xi}]\mathbf{A}^\top \\
 &= \begin{bmatrix} \mathbf{A}_x & \mathbf{A}_y \end{bmatrix} \begin{bmatrix} \mathbb{V}[\mathbf{x}] & \text{Cov}[\mathbf{x}, \mathbf{y}] \\ \text{Cov}[\mathbf{y}, \mathbf{x}] & \mathbb{V}[\mathbf{y}] \end{bmatrix} \begin{bmatrix} \mathbf{A}_x & \mathbf{A}_y \end{bmatrix}^\top \\
 &= \begin{bmatrix} \mathbf{A}_x & \mathbf{A}_y \end{bmatrix} \begin{bmatrix} \mathbb{V}[\mathbf{x}] & \text{Cov}[\mathbf{x}, \mathbf{y}] \\ \text{Cov}[\mathbf{y}, \mathbf{x}] & \mathbb{V}[\mathbf{y}] \end{bmatrix} \begin{bmatrix} \mathbf{A}_x^\top \\ \mathbf{A}_y^\top \end{bmatrix} \\
 &= \mathbf{A}_x\mathbb{V}[\mathbf{x}]\mathbf{A}_x^\top + \mathbf{A}_y\mathbb{V}[\mathbf{y}]\mathbf{A}_y^\top \\
 &\quad + \underbrace{\mathbf{A}_y\text{Cov}[\mathbf{y}, \mathbf{x}]\mathbf{A}_x^\top}_{=0\text{by independence}} + \underbrace{\mathbf{A}_x\text{Cov}[\mathbf{x}, \mathbf{y}]\mathbf{A}_y^\top}_{=0\text{by independence}} \\
 &= \mathbf{A}_x\boldsymbol{\Sigma}_x\mathbf{A}_x^\top + \mathbf{A}_y\boldsymbol{\Sigma}_y\mathbf{A}_y^\top
 \end{aligned}$$

□

**Note**

Can also be proofed by using the normal definition of <sup>[def. 23.15]</sup> and tedious computations.

## 8. Sampling Random Numbers

Most math libraries have uniform **random number generator (RNG)** i.e. functions to generate uniformly distributed random numbers  $U \sim \mathcal{U}[a, b]$  (eq. (23.50)). Furthermore repeated calls to these RNG are independent, that is:

$$\begin{aligned} \mathbb{P}_{U_1, U_2}(u_1, u_2) &\stackrel{??}{=} \mathbb{P}_{U_1}(u_1) \cdot \mathbb{P}_{U_2}(u_2) \\ &= \begin{cases} 1 & \text{if } u_1, u_2 \in [a, b] \\ 0 & \text{otherwise} \end{cases} \end{aligned}$$

**Question:** using samples  $\{u_1, \dots, u_n\}$  of these CRVs with uniform distribution, how can we create random numbers with arbitrary discret or continuous PDFs?

## 9. Inverse-transform Technique

### Idea

Can make use of section 1 and the fact that CDF are increasing functions (def. 13.10). **Advantage:**

- Simple to implement
- All discrete distributions can be generated via inverse-transform technique

### Drawback:

- Not all continuous distributions can be integrated/have closed form solution for their CDF.  
E.g. Normal-,Gamma-,Beta-distribution.

### 9.1. Continuous Case

**Definition 23.38 One Continuous Variable:** Given: a desired continuous pdf  $f_X$  and uniformly distributed rn  $\{u_1, u_2, \dots\}$ :

1. Integrate the desired pdf  $f_X$  in order to obtain the desired cdf  $F_X$ :

$$F_X(x) = \int_{-\infty}^x f_X(t) dt \quad (23.88)$$

2. Set  $F_X(X) \stackrel{!}{=} U$  on the range of  $X$  with  $U \sim \mathcal{U}[0, 1]$ .
3. Invert this equation/find the inverse  $F_X^{-1}(U)$  i.e. solve:

$$U = F_X(X) = F_X\left(\underbrace{F_X^{-1}(U)}_X\right) \quad (23.89)$$

4. Plug in the uniformly distributed rn:

$$x_i = F_X^{-1}(u_i) \quad \text{s.t.} \quad x_i \sim f_X \quad (23.90)$$

### Definition 23.39 Multiple Continuous Variable:

**Given:** a pdf of multiple rvs  $f_{X,Y}$ :

1. Use the product rule (??) in order to decompose  $f_{X,Y}$ :

$$f_{X,Y} = f_{X,Y}(x, y) = f_{X|Y}(x|y) f_Y(y) \quad (23.91)$$

2. Use [def. 23.40] to first get a rv for  $y$  of  $Y \sim f_Y(y)$ .
3. Then with this fixed  $y$  use [def. 23.40] again to get a value for  $x$  of  $X \sim f_{X|Y}(x|y)$ .

*Proof.* [def. 23.40]:

**Claim:** if  $U$  is a uniform rv on  $[0, 1]$  then  $F_X^{-1}(U)$  has  $F_X$  as its CDF.

**Assume** that  $F_X$  is strictly increasing (def. 13.10). Then for any  $u \in [0, 1]$  there must exist a **unique**  $x$  s.t.  $F_X(x) = u$ .

Thus  $F_X$  must be invertible and we may write  $x = F_X^{-1}(u)$ .

**Now** let  $a$  arbitrary:

$$F_X(a) = \mathbb{P}(\underline{x} \leq a) = \mathbb{P}(F_X^{-1}(U) \leq a)$$

Since  $F_X$  is strictly increasing:

$$\begin{aligned} \mathbb{P}(F_X^{-1}(U) \leq a) &= \mathbb{P}(U \leq F_X(a)) \\ &\stackrel{\text{eq. (23.50)}}{=} \int_0^{F_X(a)} 1 dt = F_X(a) \end{aligned}$$

□

### Note

Strictly speaking we may not assume that a CDF is **strictly** increasing but we as all CDFs are weakly increasing (def. 13.10) we may always define an auxiliary function by its infimum:

$$\hat{F}_X^{-1} := \inf \{x | F_X(x) \geq 0\} \quad u \in [0, 1] \quad (23.92)$$

### 9.2. Discret Case

#### Idea

**Given:** a desired  $U \sim \mathcal{U}[0, 1]$  and uniformly distributed rn  $\{u_1, u_2, \dots\}$ .  
**Goal:** given a uniformly distributed rn  $u$  determine  $k$  s.t.:

$$\begin{aligned} k-1 &< U \leq k \\ i=1 &\sum_{i=1}^{k-1} < U \leq \sum_{i=1}^k \iff F_X(x_{k-1}) < u \leq F_X(x_k) \end{aligned} \quad (23.93)$$

and return  $x_k$ .

### Definition 23.40 One Discret Variable:

1. Compute the CDF of  $p_X$  (def. 23.8)

$$F_X(x) = \sum_{t=-\infty}^x p_X(t) \quad (23.94)$$

2. Given the uniformly distributed rn  $\{u_i\}_{i=1}^n$  find  $k^i$  ( $\hat{=}$  inversion) s.t.:

$$F_X(x_{k(i)-1}) < u_i \leq F_X(x_{k(i)}) \quad \forall u_i \quad (23.95)$$

*Proof.* ??: First of all notice that we can always solve for an unique  $x_k$ .

**Ask:** why are Discret CRV always strictly increasing/unique?

**Given** a fixed  $x_k$  determine the values of  $u$  for which:

$$F_X(x_{k-1}) < u \leq F_X(x_k) \quad (23.96)$$

**Now** observe that:

$$\begin{aligned} u &\leq F_X(x_k) = F_X(x_{k-1}) + p_X(x_k) \\ \Rightarrow F_X(x_{k-1}) &< u \leq F_X(x_{k-1}) + p_X(x_k) \end{aligned}$$

The probability of  $U$  being in  $(F_X(x_{k-1}), F_X(x_k)]$  is:

$$\begin{aligned} \mathbb{P}(U \in [F_X(x_{k-1}), F_X(x_k)]) &= \int_{F_X(x_{k-1})}^{F_X(x_k)} p_U(t) dt \\ &= \int_{F_X(x_{k-1})}^{F_X(x_k)} 1 dt = \int_{F_X(x_{k-1})}^{F_X(x_{k-1}) + p_X(x_k)} 1 dt = p_X(x_k) \end{aligned}$$

Hence the random variable  $x_k \in \mathcal{X}$  has the pdf  $p_X$ . □

### Definition 23.41

#### Multiple Continuous Variables (Option 1):

**Given:** a pdf of multiple rvs  $p_{X,Y}$ :

1. Use the product rule (??) in order to decompose  $p_{X,Y}$ :

$$p_{X,Y} = p_{X,Y}(x, y) = p_{X|Y}(x|y) p_Y(y) \quad (23.97)$$

2. Use ?? to first get a rv for  $y$  of  $Y \sim p_Y(y)$ .
3. Then with this fixed  $y$  use ?? again to get a value for  $x$  of  $X \sim p_{X|Y}(x|y)$ .

### Definition 23.42

#### Multiple Continuous Variables (Option 2):

**Note:** this only works if  $\mathcal{X}$  and  $\mathcal{Y}$  are finite.

**Given:** a pdf of multiple rvs  $p_{X,Y}$  let  $N_x = |\mathcal{X}|$  and  $N_y = |\mathcal{Y}|$  the number of elements in  $\mathcal{X}$  and  $\mathcal{Y}$ .

**Define**  $p_Z(1) = p_{X,Y}(1, 1), p_Z(2) = p_{X,Y}(1, 2), \dots, p_Z(N_x \cdot N_y) = p_{X,Y}(N_x, N_y)$

Then simply apply ?? to the auxillary pdf  $p_Z$

1. Use the product rule (??) in order to decompose  $f_{X,Y}$ :

$$f_{X,Y} = f_{X,Y}(x, y) = f_{X|Y}(x|y) f_Y(y) \quad (23.98)$$

2. Use [def. 23.40] to first get a rv for  $y$  of  $Y \sim f_Y(y)$ .
3. Then with this fixed  $y$  use [def. 23.40] again to get a value for  $x$  of  $X \sim f_{X|Y}(x|y)$ .

See examples see comment in code text

10. Descriptive Statistics

10.1. Population Parameters

**Definition 23.43 Population/Statistical Parameter:** Are parameters defining families of probability distributions and thus characteristics of population following such distributions i.e. the normal distribution has two parameters  $\{\mu, \sigma^2\}$

**Definition 23.44 Population Mean:** Given a population  $\{x_i\}_{i=1}^N$  of size  $N$  its variance is defined as:

$$\mu = \frac{1}{N} \sum_{i=1}^N x_i \tag{23.99}$$

**Definition 23.45 Population Variance:** Given a population  $\{x_i\}_{i=1}^N$  of size  $N$  its variance is defined as:  $\{x_i\}_{i=1}^N$

$$\sigma^2 = \frac{1}{N} \sum_{i=1}^N (x_i - \mu)^2 \tag{23.100}$$

Note

The population variance and mean are equally to the mean derived from the true distribution of the population.

10.2. Sample Estimates

**Definition 23.46 (Sample) Statistic:** A statistic is a measurable function  $f$  that assigns a **single** value  $F$  to a sample of random variables or population:

$$f : \mathbb{R}^n \mapsto \mathbb{R} \qquad F = f(X_1, \dots, X_n)$$

E.g.  $F$  could be the mean, variance,...

Note

The function itself is independent of the sample's distribution; that is, the function can be stated before realization of the data.

**Definition 23.47 (Point) Estimator**  $\hat{\theta} = \hat{\theta}(\mathbf{X})$ :  
**Given:** n-samples  $\mathbf{x}_1, \dots, \mathbf{x}_n \sim \mathbf{X}$  an estimator  
 $\hat{\theta} = h(\mathbf{x}_1, \dots, \mathbf{x}_n)$  (23.101)

is a statistic/randomn variable used to estimate a true (population) parameter  $\theta$ <sup>[def. 23.43]</sup>.

Note

The other kind of estimators are interval estimators which do not calculate a statistic **but** an interval of plausible values of an unknown population parameter  $\theta$ .

The most prevalent forms of interval estimation are:

- Confidence intervals (frequentist method).
- Credible intervals (Bayesian method).

**Definition 23.48 Degrees of freedom of a Statistic:** Is the number of values in the final calculation of a statistic that are free to vary.

10.2.1. Empirical Mean

**Definition 23.49 Sample/Empirical Mean**  $\bar{x}$ :  
The sample mean is an estimate/statistic of the population mean<sup>[def. 23.44]</sup> and can be calculated from an observation/sample of the total population  $\{x_i\}_{i=1}^n \subset \{x_i\}_{i=1}^N$ :

$$\bar{x} = \hat{\mu}_X = \frac{1}{n} \sum_{i=1}^n x_i \tag{23.102}$$

**Corollary 23.6 Expectation:** The sample mean estimator is unbiased (see section 14):

$$\mathbb{E}[\hat{\mu}_X] = \mu \tag{23.103}$$

**Corollary 23.7 Variance:** For the variance of the sample mean estimator it holds (see section 14):

$$\mathbb{V}[\hat{\mu}_X] = \frac{1}{n} \sigma_X^2 \tag{23.104}$$

10.2.2. Empirical Variance

**Definition 23.50 Biased Sample Variance:** The sample mean is an estimate/statistic of the population variance<sup>[def. 23.45]</sup> and can be calculated from an observation/sample of the total population  $\{x_i\}_{i=1}^n \subset \{x_i\}_{i=1}^N$ :

$$s_n^2 = \hat{\sigma}_X^2 = \frac{1}{n} \sum_{i=1}^n (x_i - \mu)^2 \tag{23.105}$$

**Definition 23.51 (Unbiased) Sample Variance:**

$$s^2 = \hat{\sigma}_X^2 = \frac{1}{n-1} \sum_{i=1}^n (x_i - \mu)^2 \tag{23.106}$$

see section 14

**Definition 23.52 Bessel's Correction:** The factor  $\frac{n}{n-1}$  (23.107)

as multiplying the uncorrected population varianceeq. (23.105) by this term yields an unbiased estimated of the variance (not the standard deviation). The reason for this is that are

**Attention:** Usually only unbiased variance is used and also sometimes denoted by  $s_n^2$

*Proof.*

11. Statistical Tests

**Definition 23.53 Null Hypothesis:** A Null Hypothesis  $H_0$  is usually a commonly accepted fact/view/base hypothesis that researchers try to nullify or disprove.

$$H_0 : \theta = \theta_0 \tag{23.108}$$

**Definition 23.54 Alternative Hypothesis:** The Alternative Hypothesis  $H_A/H_1$  is the opposite of the Null Hypotheses/contradicts it and is what we try to test against the Null Hypothesis.

$$H_A : \theta \begin{cases} > \theta_0 & \text{(one-sided)} \\ < \theta_0 & \text{(one-sided)} \\ \neq \theta_0 & \text{(two-sided)} \end{cases} \tag{23.109}$$

**Definition 23.55 Testing Parameters:**

**Given:** a parameter  $\theta$  that we want to test.

Let  $\Theta$  be the set of all possible values that  $\theta$  can achieve.

We now split  $\Theta$  in two disjunct sets  $\Theta_0$  and  $\Theta_1$ .

$$\Theta = \Theta_0 \cup \Theta_1 \qquad \Theta_0 \cap \Theta_1 = \emptyset$$

$$\text{Null Hypothesis} \qquad H_0 : \theta \in \Theta_0 \tag{23.110}$$

$$\text{Alternative Hypothesis} \qquad H_A : \theta \in \Theta_1 \tag{23.111}$$

11.1. Type I&II Errors

**Definition 23.56 Type I Error:** Is the rejection of a Null Hypothesis, even-tough its true (also known as a "false positive").

**Definition 23.57 Type II Error:** Is the acceptance of a Null Hypothesis, even-tough its false (also known as a "false negative").

Decision	$H_0$ true	$H_0$ false	
Accept	TN	Type II (FN)	
Reject	Type I (FP)	TP	

**Definition 23.58 Critical Value c:** Value from which on the Null-hypothesis  $H_0$  gets rejected.

**Definition 23.59 Statistical significance**  $\alpha$ : A study's defined significance level, denoted  $\alpha$ , is the **probability** of the study rejecting the null hypothesis, given that the null hypothesis were true (Type I Error).

**Definition 23.60 Critical Region**  $K_\alpha$ : Is the set of all values that causes us to reject the Null Hypothesis in favor for the Alternative Hypothesis  $H_A$ .

The Critical region is usually chosen s.t. we incur a Type I Error with probability less than  $\alpha$ .

$$K_\alpha \in \Theta : \mathbb{P}(\text{Type I Error}) \leq \alpha \tag{23.112}$$

$$\begin{aligned} &\mathbb{P}(c_2 \leq X \leq c_1) \leq \alpha && \text{two-sided} \\ \text{or } &\mathbb{P}(c_2 \leq X) \leq \frac{\alpha}{2} && \text{and } \mathbb{P}(X \leq c_1) \leq \frac{\alpha}{2} \\ &\mathbb{P}(c_2 \leq X) \leq \alpha && \text{one-sided} \\ &\mathbb{P}(X \leq c_1) \leq \alpha && \text{one-sided} \end{aligned}$$

**Definition 23.61 Acceptance Region:** Is the region where we accept the null hypothesis  $H_0$ .

Note

see example 23.3.

11.2. Normally Distributed Data

Let us consider a sample of  $\{x_i\}_{i=1}^n$  i.i.d. observations, that follow a normal distribution  $x_i \sim \mathcal{N}(\mu, \sigma^2)$ .

**11.2.1. Z-Test**  $\sigma$  known

**11.2.2. t-Test**  $\sigma$  unknown

12. Inferential Statistics

Goal of Inference

- ① What is a good guess of the parameters of my model?
- ② How do I quantify my uncertainty in the guess?

13. Examples

**Example 23.1 ??:** Let  $x$  be uniformly distributed on  $[0, 1]$  (def. 23.26) with pmf  $p_X(x)$  then it follows:  
 $\frac{dy}{dx} = \frac{1}{p_Y(y)} \Rightarrow dx = dy p_Y(y) \Rightarrow x = \int_{-\infty}^y p_Y(t) dt = F_Y(x)$

**Example 23.2 ??:** Let

add <https://www.youtube.com/watch?v=WUUhTVIRagg>

**Example 23.3 Binomialtest:**  
**Given:** a manufacturer claims that a maximum of 10% of its delivered components are substandard goods.  
In a sample of size  $n = 20$  we find  $x = 5$  goods that do not fulfill the standard and are skeptical that the what the manufacture claims is true, so we want to test:  
 $H_0 : p = p_0 = 0.1$  vs.  $H_A : p > 0.1$

We model the number of number of defective goods using the binomial distribution (def. 23.23)

$$X \sim \mathcal{B}(n, p), n = 20 \quad \mathbb{P}(X \geq x) = \sum_{k=x}^n \binom{n}{k} p^k (1-p)^{n-k}$$

from this we find:

$$\mathbb{P}_{p_0}(X \geq 4) = 1 - \mathbb{P}_{p_0}(X \leq 3) = 0.13$$

$$\mathbb{P}_{p_0}(X \geq 4) = 1 - \mathbb{P}_{p_0}(X \leq 3) = 0.04 \leq \alpha$$

thus the probability that equal 5 or more then 5 parts out of the 20 are rejects is less then 4%.

$\Rightarrow$  throw away null hypothesis for the 5% niveau in favor to the alternative.

$\Rightarrow$  the 5% significance niveau is given by  $K = \{5, 6, \dots, 20\}$

**Note**

If  $x < n/2$  it is faster to calculate  $\mathbb{P}(X \geq x) = 1 - \mathbb{P}(X \leq x-1)$

14. Proofs

*Proof.* corollary 23.6:

$$\mathbb{E}[\hat{\mu}_X] = \mathbb{E}\left[\frac{1}{n} \sum_{i=1}^n x_i\right] = \frac{1}{n} \mathbb{E}\left[\sum_{i=1}^n x_i\right] = \frac{1}{n} \mathbb{E}\left[\underbrace{\mu + \dots + \mu}_{1, \dots, n}\right]$$

□

*Proof.* corollary 23.7:

$$\mathbb{V}[\hat{\mu}_X] = \mathbb{V}\left[\frac{1}{n} \sum_{i=1}^n x_i\right] \stackrel{\text{Property 23.10}}{=} \frac{1}{n^2} \mathbb{V}\left[\sum_{i=1}^n x_i\right]$$
$$\frac{1}{n^2} n \mathbb{V}[X] = \frac{1}{n} \sigma^2$$

□

*Proof.* definition 23.51:

$$\begin{aligned} \mathbb{E}[\hat{\sigma}_X^2] &= \mathbb{E}\left[\frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2\right] \\ &= \frac{1}{n-1} \mathbb{E}\left[\sum_{i=1}^n (x_i^2 - 2x_i \bar{x} + \bar{x}^2)\right] \\ &= \frac{1}{n-1} \mathbb{E}\left[\sum_{i=1}^n x_i^2 - 2\bar{x} \sum_{i=1}^n x_i + \sum_{i=1}^n \bar{x}^2\right] \\ &= \frac{1}{n-1} \mathbb{E}\left[\sum_{i=1}^n x_i^2 - 2n\bar{x} \cdot n\bar{x} + n\bar{x}^2\right] \\ &= \frac{1}{n-1} \mathbb{E}\left[\sum_{i=1}^n x_i^2 - n\bar{x}^2\right] \\ &= \frac{1}{n-1} \left[\sum_{i=1}^n \mathbb{E}[x_i^2] - n\mathbb{E}[\bar{x}^2]\right] \\ &= \frac{1}{n-1} \left[\sum_{i=1}^n (\sigma^2 + \mu^2) - n\mathbb{E}[\bar{x}^2]\right] \\ &= \frac{1}{n-1} \left[\sum_{i=1}^n (\sigma^2 + \mu^2) - n\left(\frac{1}{n}\sigma^2 + \mu^2\right)\right] \\ &= \frac{1}{n-1} \left[(n\sigma^2 + n\mu^2) - (\sigma^2 + n\mu^2)\right] \\ &= \frac{1}{n-1} [n\sigma^2 - \sigma^2] = \frac{1}{n-1} [(n-1)\sigma^2] = \sigma^2 \end{aligned}$$

□

Stochastic Calculus

Stochastic Processes

**Definition 24.1 Random/Stochastic Process**  $\{X_t, t \in \mathcal{T} \subseteq \mathbb{R}_+\}$ : is a collection of random variables on the same probability space  $(\Omega, \mathcal{A}, \mathbb{P})$ . The index set  $\mathcal{T}$  is usually representing time and can be either an interval  $[t_1, t_2]$  or a discrete set  $\{t_1, t_2, \dots\}$ . Therefore, the random process  $X$  can be written as a function:

$$X: \mathbb{R} \times \Omega \mapsto \mathbb{R} \iff (t, \omega) \mapsto X(t, \omega) \quad (24.1)$$

**Definition 24.2 Sample path/Trajectory/Realization:** Is the *stochastic/noise signal*  $r(\cdot, \omega)$  on the index set  $\mathcal{T}$ , that we obtain be sampling  $\omega$  from  $\Omega$ .

**Notation**  
Even though the r.v.  $X$  is a function of two variables, most books omit the argument of the sample space  $X(t, \omega) := X(t)$

**Definition 24.3 Filtration**  $\mathbb{F} = \{\mathcal{F}_t\}_{t \geq 0}$ : A collection  $\{\mathcal{F}_t\}_{t \geq 0}$  of sub  $\sigma$ -algebras  $\{\mathcal{F}_t\}_{t \geq 0} \in \mathcal{F}$  is called filtration if is *increasing*:

$$\mathcal{F}_s \subseteq \mathcal{F}_t \quad \forall s \leq t \quad (24.2)$$

**Definition 24.4 Adapted Process:** A stochastic process  $\{X_t : 0 \leq t \leq \infty\}$  is called adapted to a filtration  $\mathbb{F}$  if,  $X_t$  is  $\{\mathcal{F}_{t-1}\}$ -measurable, i.e. the value of  $X_t$  is known at time  $t-1$ .

**Definition 24.5 Predictable Process:** A stochastic process  $\{X_t : 0 \leq t \leq \infty\}$  is called predictable w.r.t. a filtration  $\mathbb{F}$  if,  $X_t$  is  $\{\mathcal{F}_{t-1}\}$ -measurable, i.e. the value of  $X_t$  is known at time  $t-1$ .

**Note**  
The price of a stock will usually be adapted since date  $k$  prices are known at date  $k$ .  
On the other hand the interest rate of a bank account is usually already known at the beginning  $k-1$ , s.t. the interest rate  $r_t$  ought to be  $\mathcal{F}_{k-1}$  measurable, i.e. the process  $r = (r_k)_{k=1, \dots, T}$  should be predictable.

**Definition 24.6 Filtered Probability Space**  $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t \geq 0}, \mathbb{P})$ : A probability space  $(\Omega, \mathcal{F}, \mathbb{P})$  together with a filtration  $\{\mathcal{F}_t\}_{t \geq 0}$  is called a *filtered probability space*.

**Corollary 24.1** : The amount of information of an adapted random process is increasing see example 24.1.

**Definition 24.7 Martingales:** A stochastic process  $X(t)$  is a martingale on a *filtered probability space*  $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t \geq 0}, \mathbb{P})$  if the following conditions hold:

- Given  $s \leq t$  the best prediction of  $X(t)$ , with a filtration  $\{\mathcal{F}_s\}$  is the current expected value:  
$$\forall s \leq t \quad \mathbb{E}[X(t)|\mathcal{F}_s] = X(s) \quad \text{a.s.} \quad (24.3)$$
- The expectation is finite:  
$$\mathbb{E}[|X(t)|] < \infty \quad \forall t \geq 0 \quad X(t) \text{ is } \{\mathcal{F}_t\}_{t \geq 0} \text{ adapted} \quad (24.4)$$

**Interpretation**

- For any  $\mathcal{F}_s$ -adapted process the best prediction of  $X(t)$  is the currently known value  $X(s)$  i.e. if  $\mathcal{F}_s = \mathcal{F}_{t-1}$  then the best prediction is  $X(t-1)$
- A martingale models fair games of limited information.

**Definition 24.8 Auto Covariance**  $\gamma(t_2 - t_1)$ : Describes the covariance<sup>[def. 23.16]</sup> between two values of a stochastic process  $(X_t)_{t \in \mathcal{T}}$  at different time points  $t_1$  and  $t_2$ .

$$\gamma(t_1, t_2) = \text{Cov}[X_{t_1}, X_{t_2}] = \mathbb{E}[(X_{t_1} - \mu_{t_1})(X_{t_2} - \mu_{t_2})] \quad (24.5)$$

For zero time differences  $t_1 = t_2$  the autocorrelation functions equals the variance:

$$\gamma(t, t) = \text{Cov}[X_t, X_t] \stackrel{\text{eq. (23.35)}}{=} \mathbb{V}[X_t] \quad (24.6)$$

**Notes**

- Hence the autocorrelation describes the correlation of a function or signal with itself at a previous time point.
- Given a random time dependent variable  $\mathbf{x}(t)$  the autocorrelation function  $\gamma(t, t - \tau)$  describes how *similar* the time translated function  $\mathbf{x}(t - \tau)$  and the original function  $\mathbf{x}(t)$  are.
- If there exists some relation between the values of the time series that is non-random, then the autocorrelation is non-zero.
- The auto covariance is maximized/most similar for no translation  $\tau = 0$  at all.

**Definition 24.9 Auto Correlation**  $\rho(t_2 - t_1)$ : Is the scaled version of the auto-covariance<sup>[def. 24.8]</sup>:

$$\begin{aligned} \rho(t_2 - t_1) &= \text{Corr}[X_{t_1}, X_{t_2}] \\ &= \frac{\text{Cov}[X_{t_1}, X_{t_2}]}{\sigma_{X_{t_1}} \sigma_{X_{t_2}}} = \frac{\mathbb{E}[(X_{t_1} - \mu_{t_1})(X_{t_2} - \mu_{t_2})]}{\sigma_{X_{t_1}} \sigma_{X_{t_2}}} \end{aligned} \quad (24.7)$$

1. Different kinds of Processes

1.1. Markov Process

**Definition 24.10 Markov Process:** A continuous-time stochastic process  $X(t), t \in T$ , is called a Markov process if for any finite parameter set  $\{t_i : t_i < t_{i+1}\} \in T$  it holds:

$$\mathbb{P}(X(t_{n+1}) \in B | X(t_1), \dots, X(t_n)) = \mathbb{P}(X(t_{n+1}) \in B | X(t_n))$$

it thus follows for the *transition probability* – the probability of  $X(t)$  lying in the set  $B$  at time  $t$ , given the value  $x$  of the process at time  $s$ :

$$\mathbb{P}(s, x, t, B) = P(X(t) \in B | X(s) = x) \quad 0 \leq s < t \quad (24.8)$$

**Interpretation**  
In order to predict the future only the current/last value counts.

**Corollary 24.2 Transition Density:** The transition probability of a continuous distribution  $\mathbf{p}$  can be calculated via:

$$\mathbb{P}(s, x, t, B) = \int_B \mathbf{p}(s, x, t, y) dy \quad (24.9)$$

1.2. Gaussian Process

**Definition 24.11 Gaussian Process:** Is a stochastic process  $X(t)$  where the random variables follow a Gaussian distribution:

$$X(t) \sim \mathcal{N}(\mu(t), \sigma^2(t)) \quad \forall t \in T \quad (24.10)$$

1.3. Diffusions

**Definition 24.12 Diffusion:** Is a Markov Process<sup>[def. 24.10]</sup> for which it holds that:

$$\begin{aligned} \mu(t, X(t)) &= \lim_{t \rightarrow 0} \frac{1}{\Delta t} \mathbb{E}[X(t + \Delta t) - X(t) | X(t)] \quad (24.11) \\ \sigma^2(t, X(t)) &= \lim_{t \rightarrow 0} \frac{1}{\Delta t} \mathbb{E}[(X(t + \Delta t) - X(t))^2 | X(t)] \quad (24.12) \end{aligned}$$

See ??/eq. (24.12) for simple proof of eq. (24.11)/??.

- $\mu(t, X(t))$  is called **drift**
- $\sigma^2(t, X(t))$  is called **diffusion coefficient**

**Interpretation**  
There exist not discontinuities for the trajectories.

1.4. Brownian Motion/Wiener Process

**Definition 24.13 d-dim standard Brownian Motion/Wiener Process:** Is an  $\mathbb{R}^d$  valued *stochastic process*<sup>[def. 24.1]</sup>  $(W_t)_{t \in \mathcal{T}}$  starting at  $\mathbf{x}_0 \in \mathbb{R}^d$  that satisfies:

① **Normal Independent Increments:** the increments are *normally distributed independent random variables*:

$$W(t_i) - W(t_{i-1}) \sim \mathcal{N}(0, (t_i - t_{i-1}) \mathbb{1}_{d \times d}) \quad \forall i \in \{1, \dots, T\} \quad (24.13)$$

② **Stationary increments:**  $W(t + \Delta t) - W(t)$  is independent of  $t \in \mathcal{T}$

③ **Continuity:** for a.e.  $\omega \in \Omega$ , the function  $t \mapsto W_t(\omega)$  is continuous

$$\lim_{t \rightarrow 0} \frac{\mathbb{P}(|W(t + \Delta t) - W(t)| \geq \delta)}{\Delta t} = 0 \quad \forall \delta > 0 \quad (24.14)$$

④ **Start**

$$W(0) := W_0 = 0 \quad \text{a.s.} \quad (24.15)$$

**Notation**

- In many source the Brownian motion is a synonym for the standard Brownian Motion and it is the same as the Wiener process.
- However in some sources the Wiener process is the standard Brownian Motion, while the Brownian motion denotes a general form  $\alpha W(t) + \beta$ .

**Corollary 24.3**  $W_t \sim \mathcal{N}(0, \sigma)$ : The random variable  $W_t$  follows the  $\mathcal{N}(0, \sigma)$  law

$$\begin{aligned} \mathbb{E}[W(t)] &= \mu = 0 \quad (24.16) \\ \mathbb{V}[W(t)] &= \mathbb{E}[W^2(t)] = \sigma^2 = t \quad (24.17) \end{aligned}$$

See section 5

1.4.1. Properties of the Wiener Process

**Property 24.1 Non-Differentiable Trajectories:** The sample paths of a Brownian motion are not differentiable:

$$\begin{aligned} \frac{dW(t)}{dt} &= \lim_{t \rightarrow 0} \mathbb{E} \left[ \left( \frac{W(t + \Delta t) - W(t)}{\Delta t} \right)^2 \right] \\ &= \lim_{t \rightarrow 0} \frac{\mathbb{E}[W(t + \Delta t) - W(t)]}{\Delta t} = \lim_{t \rightarrow 0} \frac{\sigma^2}{\Delta t} = \infty \end{aligned}$$

$\xrightarrow{\text{result}}$  cannot use normal calculus anymore  
 $\xrightarrow{\text{solution}}$  Ito Calculus see section 25.

**Property 24.2 Auto covariance Function:** The auto-covariance<sup>[def. 24.8]</sup> for a Wiener process

$$\mathbb{E}[(W(t) - \mu(t))(W(t') - \mu(t'))] = \min(t, t') \quad (24.18)$$

**Property 24.3:** A standard Brownian motion is a **Quadratic Variation**

**Definition 24.14 Total Variation:** The total variation of a function  $f: [a, b] \subset \mathbb{R} \mapsto \mathbb{R}$  is defined as:

$$LV_{[a,b]}(f) = \sup_{\Pi \in \mathcal{S}} \sum_{i=0}^{n_{\Pi}-1} |f(x_{i+1}) - f(x_i)| \quad (24.19)$$

$\mathcal{S} = \{\Pi\{x_0, \dots, x_{n_{\Pi}}\} : \Pi \text{ is a partition } ^{[\text{def. 19.8}]} \text{ of } [a, b]\}$   
it is a measure of the (one dimensional) length of a function w.r.t. to the y-axis, when moving alone the function.  
Hence it is a measure of the variation of a function w.r.t. to the y-axis.

**Definition 24.15 Total Quadratic Variation/“sum of squares”:** The total quadratic variation of a function  $f: [a, b] \subset \mathbb{R} \mapsto \mathbb{R}$  is defined as:

$$QV_{[a,b]}(f) = \sup_{\Pi \in \mathcal{S}} \sum_{i=0}^{n_{\Pi}-1} |f(x_{i+1}) - f(x_i)|^2 \quad (24.20)$$

$\mathcal{S} = \{\Pi\{x_0, \dots, x_{n_{\Pi}}\} : \Pi \text{ is a partition } ^{[\text{def. 19.8}]} \text{ of } [a, b]\}$

**Corollary 24.4 Bounded (quadratic) Variation:** The (quadratic) variation<sup>[def. 24.14]</sup> of a function is bounded if it is finite:

$$\exists M \in \mathbb{R}_+ : LV_{[a,b]}(f) \leq M \iff (QV_{[a,b]}(f) \leq M) \quad \forall \Pi \in \mathcal{S} \quad (24.21)$$

**Theorem 24.1 Variation of Wiener Process:** Almost surely the total variation of a Brownian motion over a interval  $[0, T]$  is infinite:

$$\mathbb{P}(\omega : LV(W(\omega)) < \infty) = 0 \quad (24.22)$$

**Theorem 24.2 Quadratic Variation of standard Brownian Motion:** The quadratic variation of a standard Brownian motion over  $[0, T]$  is finite:

$$\lim_{N \rightarrow \infty} \sum_{k=1}^N \left[ W\left(k \frac{T}{N}\right) - W\left((k-1) \frac{T}{N}\right) \right]^2 = T$$

with probability 1

See ??

**Corollary 24.5** : theorem 24.2 can also be written as:

$$(dW(t))^2 = dt \quad (24.24)$$

1.4.2. Lévy’s Characterization of BM

**Theorem 24.3 d-dim standard BM/Wiener Process by Paul Lévy:** An  $\mathbb{R}^d$  valued *adapted stochastic process*<sup>[def’s. 24.1, 24.3]</sup>  $(W_t)_{t \in \mathcal{T}}$  with the filtration  $\{\mathcal{F}_t\}_{t \in \mathbb{R}_+}$ , that satisfies:

① **Start**

$$W(0) := W_0 = 0 \quad \text{a.s.} \quad (24.25)$$

② **Continuous Martingale:**  $W_t$  is an a.s. *continuous martingale*<sup>[def. 24.7]</sup> w.r.t. the filtration  $(\mathcal{F}_t)_{t \in \mathcal{T}}$  under  $\mathbb{P}$ .

③ **Quadratic Variation:**  $W_t^2 - t$  is also an martingale  $\iff QV(W_t) = t$

$$(24.26)$$

is a standard Brownian motion<sup>[def. 24.20]</sup>. Proof see section 5

Further Stochastic Processes

1.4.3. White Noise

**Understand script and add**

**Definition 24.16 Discrete-time white noise:** Is a random signal  $\{\epsilon_t\}_{t \in T_{\text{discret}}}$  having equal intensity at different frequencies and is defined by:

- Having zero tendencies/expectation (otherwise the signal would not be random):  
$$\mathbb{E}[\epsilon * [k]] = 0 \quad \forall k \in T_{\text{discret}} \quad (24.27)$$

- Zero autocorrelation<sup>[def. 24.9]</sup>  $\gamma$  i.e. the signals of different times are in no-way correlated:  
$$\gamma(\epsilon * [k], \epsilon * [k + n]) = \mathbb{E}[\epsilon * [k] \epsilon * [k + n]^T] = \mathbb{V}[\epsilon * [k]] \delta_{\text{discret}}[n] \quad \forall k, n \in T_{\text{discret}} \quad (24.28)$$

**With**  $\delta_{\text{discret}}[n] := \begin{cases} 1 & \text{if } n = 0 \\ 0 & \text{else} \end{cases}$

See proofs

**Definition 24.17 Continuous-time white noise:** Is a random signal  $(\epsilon_t)_{t \in T_{\text{continuous}}}$  having equal intensity at different frequencies and is defined by:

- Having zero tendencies/expectation (otherwise the signal would not be random):  
$$\mathbb{E}[\epsilon * (t)] = 0 \quad \forall t \in T_{\text{continuous}} \quad (24.29)$$

- Zero autocorrelation<sup>[def. 24.9]</sup>  $\gamma$  i.e. the signals of different times are in no-way correlated:  
$$\gamma(\epsilon * (t), \epsilon * (t + \tau)) = \mathbb{E}[\epsilon * (t) \epsilon * (t + \tau)^T] \stackrel{\text{eq. (23.86)}}{=} \mathbb{V}[\epsilon * (t)] \delta(t - \tau) = \begin{cases} \mathbb{V}[\epsilon * (t)] & \text{if } \tau = 0 \\ 0 & \text{else} \end{cases} \quad (24.30)$$

$$\forall t, \tau \in T_{\text{continuous}} \quad (24.31)$$

**Definition 24.18 Homoscedastic Noise:** Is constant for all observations/time-steps:

$$\forall [\epsilon_t] = \sigma^2 \quad \forall t = 1, \dots, T \quad (24.32)$$

**Definition 24.19 Heteroscedastic Noise:** Is noise that can vary with each observation/time-step:

$$\forall [\epsilon_t] = \sigma(t)^2 \quad \forall t = 1, \dots, T \quad (24.33)$$

#### 1.4.4. Generalized Brownian Motion

**Definition 24.20 Brownian Motion:** Let  $\{W_t\}_{t \in \mathbb{R}_+}$  be a standard Brownian motion<sup>[def. 24.13]</sup>, and define:

$$X_t = \mu t + \sigma W_t \quad t \in \mathbb{R}_+ \quad \begin{array}{l} \mu \in \mathbb{R} : \text{drift parameter} \\ \sigma \in \mathbb{R}_+ : \text{scale parameter} \end{array} \quad (24.34)$$

then  $\{X_t\}_{t \in \mathbb{R}_+}$  is normally distributed with mean  $\mu t$  and variance  $t\sigma^2$   $X_t \sim \mathcal{N}(\mu t, \sigma^2 t)$ .

**Theorem 24.4 Normally Distributed Increments:** If  $W(T)$  is a Brownian motion, then  $W(t) - W(0)$  is a normal random variable with mean  $\mu t$  and variance  $\sigma^2 t$ , where  $\mu, \sigma \in \mathbb{R}$ . From this it follows that  $W(t)$  is distributed as:

$$f_{W(t)}(x) \sim \mathcal{N}(\mu t, \sigma^2 t) = \frac{1}{\sqrt{2\pi\sigma^2 t}} \exp\left\{-\frac{(x - \mu t)^2}{2\sigma^2 t}\right\} \quad (24.35)$$

**Corollary 24.6 :** More generally we may define the process:  $t \mapsto f(t) + \sigma W_t$  (24.36) which corresponds to a noisy version of  $f$ .

**Corollary 24.7 Brownian Motion as a Solution of an SDE:** A stochastic process  $X_t$  follows a BM with drift  $\mu$  and scale  $\sigma$  if it satisfies the following SDE:

$$\begin{aligned} dX(t) &= \mu dt + \sigma dW(t) & (24.37) \\ X(0) &= 0 & (24.38) \end{aligned}$$

#### 1.4.5. Geometric Brownian Motion (GBM)

For many processes  $X(t)$  it holds that:

- there exists an (exponential) growth
- that the values may not be negative  $X(t) \in \mathbb{R}_+$

**Definition 24.21 Geometric Brownian Motion:** Let  $\{W_t\}_{t \in \mathbb{R}_+}$  be a standard Brownian motion<sup>[def. 24.13]</sup> the exponential transform:

$$X(t) = \exp(W(t)) = \exp(\mu t + \sigma W(t)) \quad t \in \mathbb{R}_+ \quad (24.39)$$

is called geometric Brownian motion

**Corollary 24.8 Log-normal Returns:** For a geometric BM we obtain log-normal returns:

$$\ln\left(\frac{S_t}{S_0}\right) = \mu t + \sigma W(t) \iff \mu t + \sigma W(t) \sim \mathcal{N}(\mu t, \sigma^2 t) \quad (24.40)$$

meaning that the mean and the variance of the process (stock) *log-returns* grow over time linearly.

**Corollary 24.9 Geometric BM as a Solution of an SDE:** A stochastic process  $X_t$  follows a geometric BM with drift  $\mu$  and scale  $\sigma$  if it satisfies the following SDE:

$$\begin{aligned} dX(t) &= X(t) (\mu dt + \sigma dW(t)) & (24.41) \\ &= \mu X(t) dt + \sigma X(t) dW(t) & (24.42) \\ X(0) &= 0 \end{aligned}$$

#### 1.4.6. Locally Brownian Motion

**Definition 24.22 Locally Brownian Motion:** Let  $\{W_t\}_{t \in \mathbb{R}_+}$  be a standard Brownian motion<sup>[def. 24.13]</sup> a local Brownian motion is a stochastic process  $X(t)$  that satisfies the SDE:

$$dX(t) = \mu(X(t), t) dt + \sigma(X(t), t) dW(t) \quad (24.43)$$

#### Note

A local Brownian motion is an generalization of a geometric Brownian motion.

#### 1.4.7. Ornstein-Uhlenbeck Process

**Definition 24.23 Ornstein-Uhlenbeck Process:** Let  $\{W_t\}_{t \in \mathbb{R}_+}$  be a standard Brownian motion<sup>[def. 24.13]</sup> a Ornstein-Uhlenbeck Process or exponentially correlated noise is a stochastic process  $X(t)$  that satisfies the SDE:

$$dX(t) = -aX(t) dt + b\sigma dW(t) \quad a > 0 \quad (24.44)$$

#### 1.5. Poisson Processes

**Definition 24.24 Rare/Extreme Events:** Are events that lead to discontinuous in stochastic processes.

#### Problem

A Brownian motion is not sufficient as model in order to describe extreme events s.a. crashes in financial market time series. Need a model that can describe such discontinuities/jumps.

**Definition 24.25 Poisson Process:** A Poisson Process with rate  $\lambda \in \mathbb{R}_{\geq 0}$  is a collection of random variables  $X(t)$ ,  $t \in [0, \infty)$  defined on a probability space  $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t \geq 0}, \mathbb{P})$ , having a discrete *state space*  $N = \{0, 1, 2, \dots\}$  and satisfies:

1.  $X_0 = 0$
2. The increments follow a Poisson distribution<sup>[def. 23.25]</sup>:  

$$\mathbb{P}((X_t - X_s) = k) = \frac{\lambda(t-s)}{k!} e^{-\lambda(t-s)} \quad 0 \leq s < t < \infty \quad \forall k \in \mathbb{N}$$
3. No correlation of (non-overlapping) increments:  
 $\forall t_0 < t_1 < \dots < t_n$  : the increments are independent  
 $X_{t_1} - X_{t_0}, X_{t_2} - X_{t_1}, \dots, X_{t_n} - X_{t_{n-1}} \quad (24.45)$

#### Interpretation

A Poisson Process is a *continuous-time* process with *discrete, positive* realizations in  $\mathbb{N}_{\geq 0}$

**Corollary 24.10 Probability of events:** Using Taylor in order to expand the Poisson distribution one obtains:

$$\mathbb{P}(X_{(t+\Delta t)} - X_t \neq 0) = \lambda \Delta t + o(\Delta t^2) \quad t \text{ small i.e. } t \rightarrow 0 \quad (24.46)$$

1. Thus the probability of an event happening during  $\Delta t$  is proportional to time period and the rate  $\lambda$
2. The probability of two or more events to happen *during*  $\Delta t$  is of order  $o(\Delta t^2)$  and thus extremely small (as *Deltat* is small).

**Definition 24.26 Differential of a Poisson Process:** The differential of a Poisson Process is defined as:

$$dX_t = \lim_{\Delta t \rightarrow dt} (X_{(t+\Delta t)} - X_t) \quad (24.47)$$

**Property 24.4 Probability of Events for differential:** With the definition of the differential and using the previous results from the Taylor expansion it follows:

$$\begin{aligned} \mathbb{P}(dX_t = 0) &= 1 - \lambda & (24.48) \\ \mathbb{P}(|dX_t| = 1) &= \lambda & (24.49) \end{aligned}$$

#### Proofs

*Proof.* eq. (24.11):

Let by  $\delta$  denote the displacement of a particle at each step, and assume that the particles start at the center i.e.  $x(0) = 0$ , then we have:

$$\begin{aligned} \mathbb{E}[x(n)] &= \mathbb{E}\left[\frac{1}{N} \sum_{i=1}^N x_i(n)\right] = \frac{1}{N} \sum_{i=1}^N \mathbb{E}[x_i(n-1) \pm \delta] \\ &= \frac{1}{N} \sum_{i=1}^N \mathbb{E}[x_i(n-1)] \\ &\stackrel{\text{induction}}{=} \mathbb{E}[x_{n-1}] = \dots = \mathbb{E}[x(0)] = 0 \end{aligned}$$

Thus in expectation the particles goes nowhere.  $\square$

*Proof.* eq. (24.12):

Let by  $\delta$  denote the displacement of a particle at each step, and assume that the particles start at the center i.e.  $x(0) = 0$ , then we have:

$$\begin{aligned} \mathbb{E}[x(n)^2] &= \mathbb{E}\left[\frac{1}{N} \sum_{i=1}^N x_i(n)^2\right] = \frac{1}{N} \sum_{i=1}^N \mathbb{E}[x_i(n-1) \pm \delta]^2 \\ &= \frac{1}{N} \sum_{i=1}^N \mathbb{E}[x_i(n-1)^2 \pm 2\delta x_i(n-1) + \delta^2] \\ &\stackrel{\text{ind.}}{=} \mathbb{E}[x_{n-1}^2] + \delta^2 = \mathbb{E}[x_{n-2}^2] + 2\delta^2 = \dots \\ &= \mathbb{E}[x(0)^2] + n\delta^2 = n\delta^2 \end{aligned}$$

as  $n = \frac{\text{time}}{\text{step-size}} = \frac{t}{\Delta x}$  it follows:

$$\sigma^2 = \mathbb{E}[x^2(n)] - \mathbb{E}[x(n)]^2 = \mathbb{E}[x^2(n)] = \frac{\delta^2}{\Delta x} t \quad (24.50)$$

Thus in expectation the particles goes nowhere.  $\square$

*Proof.* eq. (24.30):

$$\begin{aligned} \gamma(\epsilon * [k], \epsilon * [k+n]) &= \text{Cov}[\epsilon * [k], \epsilon * [k+1]] \\ &= \mathbb{E}[(\epsilon * [k] - \mathbb{E}[\epsilon * [k]]) (\epsilon * [k+n] - \mathbb{E}[\epsilon * [k+n]])] \\ &\stackrel{\text{eq. (24.27)}}{=} \mathbb{E}[(\epsilon * [k]) (\epsilon * [k+n])] \end{aligned} \quad \square$$

*Proof.* corollary 24.3:

Since  $B_t - B_s$  is the increment over the interval  $[s, t]$ , it is the same in distribution as the increment over the interval  $[s-s, t-s] = [0, t-s]$

$$\begin{aligned} \text{Thus} \quad B_t - B_s &\sim B_{t-s} - B_0 \\ \text{but as } B_0 &\text{ is a.s. zero by definition eq. (24.15) it follows:} \\ B_t - B_s &\sim B_{t-s} \quad B_{t-s} \sim \mathcal{N}(0, t-s) \end{aligned} \quad \square$$

*Proof.* corollary 24.3:

$$\begin{aligned} W(t) &= W(t) - \underbrace{W(0)}_{=0} \sim \mathcal{N}(0, t) \\ \Rightarrow \quad \mathbb{E}[X] &= 0 \quad \mathbb{V}[X] = \mathbb{E}[X^2] - \mathbb{E}[X]^2 = t \end{aligned} \quad \square$$

*Proof.* theorem 24.2:

$$\begin{aligned} \sum_{k=0}^{N-1} [W(t_k) - W(t_{k-1})]^2 & \quad t_k = k \frac{T}{N} \\ &= \sum_{k=0}^{N-1} X_k^2 \quad X_k \sim \mathcal{N}\left(0, \frac{T}{N}\right) \\ &= \sum_{k=0}^{N-1} Y_k = n \left(\frac{1}{n} \sum_{k=0}^{N-1} Y_k\right) \quad \mathbb{E}[Y_k] = \frac{T}{N} \\ &\stackrel{\text{S.L.L.N}}{=} \frac{T}{n} = T \end{aligned} \quad \square$$

*Proof.* theorem 24.3 ②:

1. first we need to show eq. (24.3):  $\mathbb{E}[W_t | \mathcal{F}_s] = W_s$   
Due to the fact that  $W_t$  is  $\mathcal{F}_t$  measurable i.e.  $W_t \in \mathcal{F}_t$  we know that:

$$\begin{aligned} \mathbb{E}[W_t | \mathcal{F}_t] &= W_t & (24.51) \\ \mathbb{E}[W_t | \mathcal{F}_s] &= \mathbb{E}[W_t - W_s + W_s | \mathcal{F}] \\ &= \mathbb{E}[W_t - W_s | \mathcal{F}_s] + \mathbb{E}[W_s | \mathcal{F}_s] \\ &\stackrel{\text{eq. (24.51)}}{=} \mathbb{E}[W_t - W_s] + W_s \\ &\stackrel{W_t - W_s \sim \mathcal{N}(0, t-s)}{=} W_s \end{aligned}$$

2. second we need to show eq. (24.4):  $\mathbb{E}[|X(t)|] < \infty$

$$\mathbb{E}[|W(t)|]^2 \stackrel{??}{\leq} \mathbb{E}[|W(t)|^2] = \mathbb{E}[W^2(t)] = t < \infty \quad \square$$

*Proof.* theorem 24.3 ③:  $W_t^2 - t$  is a martingale?  
Using the binomial formula we can write and adding  $W_s - W_s$ :

$$W_t^2 = (W_t - W_s)^2 + 2W_s(W_t - W_s) + W_s^2$$

using the expectation:

$$\begin{aligned} \mathbb{E}[W_t^2 | \mathcal{F}_s] &= \mathbb{E}[(W_t - W_s)^2 | \mathcal{F}_s] + \mathbb{E}[2W_s(W_t - W_s) | \mathcal{F}_s] \\ &\quad + \mathbb{E}[W_s^2 | \mathcal{F}_s] \\ &\stackrel{\text{eq. (24.51)}}{=} \mathbb{E}[(W_t - W_s)^2] + 2W_s \mathbb{E}[(W_t - W_s)] + W_s^2 \\ &\stackrel{\text{eq. (24.17)}}{=} \mathbb{V}[W_t - W_s] + 0 + W_s^2 \\ &\quad t - s + W_s^2 \end{aligned}$$

from this it follows that:

$$\mathbb{E}[W_t^2 - t | \mathcal{F}_s] = W_s^2 - s \quad \square$$

understand why  $\mathbb{E}[(W_t - W_s)^2 | \mathcal{F}] = \mathbb{E}[(W_t - W_s)^2]$

#### Examples

**Example 24.1 :**

Suppose we have a sample space of four elements:  $\Omega = \{\omega_1, \omega_2, \omega_3, \omega_4\}$ . At time zero, we do not have any information about which  $\omega$  has been chosen. At time  $T/2$  we know whether we have  $\{\omega_1, \omega_2\}$  or  $\{\omega_3, \omega_4\}$ . At time  $T$ , we have full information.

$$\mathcal{F} = \begin{cases} \{\emptyset, \Omega\} & t \in [0, T/2) \\ \{\emptyset, \{\omega_1, \omega_2\}, \{\omega_3, \omega_4\}, \Omega\} & t \in [T/2, T) \\ \mathcal{F}_{\max} = 2^\Omega & t = T \end{cases} \quad (24.52)$$

Thus,  $\mathcal{F}_0$  represents initial information whereas  $\mathcal{F}_\infty$  represents full information (all we will ever know). Hence, a stochastic process is said to be defined on a filtered probability space  $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t \geq 0}, \mathbb{P})$ .

## Ito Calculus
